FEEDBACK... FEEDBACK!

It's like being there—right here in our offices! How? Just take advantage of our FEEDBACK card on page 17. You'll notice a feedback number at the beginning of each article and column. We'd like you to rate what you read so that we can print what types of things you like best. And then we will draw one Feedback card each month for a free subscription to 73.

Contract: By reading this fine print you have just entered into a binding agreement with 73 Amateur Radio Today to introduce one person to amateur radio within the next 30 days. Why not share some back issues of 73 with them? Invite them into your shack and let 'em make a few contacts. Let us know how you do.

NEVER SAY DIE

Wayne Green W2NSD/1

Being One's Best

While watching one of Perot's commercials a few days before the election, I took particular note of a comment made by both Ross's family and friends that he urged them to not just be good or better, but to be the very best they could be in life. This is a philosophy worthy of consideration. It got me to thinking . . . have I done my best to be the best? How about you?

Here you are, a licensed amateur. That means you've passed the license exam. Did you do it the easy way, by memorizing the Q&As? Or did you buckle down and learn the theory which you were being tested on? And since you've gotten your ticket have you been trying to learn more? I wish I didn't know the answer to that.

As an amateur you have the opportunity to get involved with a wide variety of activities. How much advantage have you taken of this incredible opportunity? Are you marking time through what's left of your life talking about nothing at great length on 2m or one of the low bands?

Being the best in amateur radio means different things to different folks. To me it means learning as much as you can. It means exploring every mode and every band. It means working DX, going on DXpeditions, working packet, RTTY, SSTV, moonbounce, OSCAR, transmitter hunts, ham club work, helping put on hamfests, helping with emergencies, handling traffic, helping newcomers get licensed, building equipment, winning contests, running a repeater, pioneering new modes or technologies, making friends for America in other countries, and even serving your country in time of war.

Then there's being your best at your work. What a shame it is when parents don't teach their children the importance of being their very best. To me that means knowing more about my work than my competitors. It means endlessly doing my homework . . . which isn't actually work because it's fun. It means attending conferences, taking classes, reading books, subscribing to magazines. I just bought a new stack of books and am working my way through them. Some are tedious to read because they're so poorly written, but most are wonderful and give me lots of ideas.

When I took on my responsibility as a member of the New Hampshire Economic Development Commission I refused to let the politicians and their efforts to block the Commission from doing anything of significance hold me back. Ross's idea resonated with me.

Whenever I take up a new interest I tend to go at it whole hog. When I got interested in horseback riding I took lessons . . . and more lessons. I found better and better experts and soon I was teaching riding instructors myself. When I got into sports car rallying I first learned to navigate and then to drive. I developed a new navigation system which filled shelves with trophies. I needed special watches which would keep time accurately all day so I found a factory in Germany to make them for me and I imported them. I discovered a special pepper-grinder-like calculator used in Europe for currency conversions, but which was ideal for rallying. I went to the Curta factory in Liechtenstein and made a deal to import them for rallyists. I developed and printed my own rally tables, which were incredibly simple compared to those made by others. My customers were soon winning all the rallies.

When I got interested in photography I read books, took lessons and spent endless hours in the school darkroom building my skills. I armed myself with everything from 35mm to 5x7 cameras. This helped me greatly when I became a TV cameraman at WPIX in New York and knew how to compose pictures . . . and later when I was a TV director in Dallas and in Cleveland, I helped my cameramen get great pictures. In my early publishing days I took most of my own pictures.

I didn't take up skiing until I was 44, but then I went at it furiously. I took lessons and more lessons. In just a few weeks I was skiing better than I ever thought I'd be able to in my life. So I took even more lessons. Now, at 70, I'm brittle and thus a bit more cautious in the trails I ski since breaking something would be extremely inconvenient, but I still tear down the mountains, having more fun than should be legal.

Somehow my parents got across to me the concept of trying to be the best I could at whatever I got interested in. I've been preaching this idea in my editorials, hoping others would see the

value of this approach to life and adopt it. So how about you? Do you settle for less than the best in what you do? Are you the best at work? Are you achieving your best in amateur radio? Are you learning all you can or are you cheating yourself? When you goldbrick through life you're only cheating yourself.

Let's see, what is there to do in amateur radio that I haven't done yet? What new challenge is there for me? What challenge is there for you? What haven't you done yet? Why not? What are your excuses?

Chess

How's your chess game? Chess is a wonderful game to teach kids because it's totally skill, with no chance element whatever. When you get involved with chess you soon discover that the more you learn about the game, the better you play. A good player will always trounce a lesser player. Ah! So how does one get to be a good player? You do that the same way you get good at anything else . . . you read a lot about it and you take some lessons from an expert. You'll have to memorize hundreds of openings, and thousands of end-game closings. You learn to be aggressive or lose. The fact is that the game of chess is a wonderful teacher for life. It'll teach you the fundamentals of business. You'll learn to do your homework, be aggressive, and look for creative new approaches to old situations. You'll learn the value of persistence.

Go is another game of skill and its popularity in Asia has a good deal to do with the way the Asian countries have been running circles around us in business. Chess and Go teach qualities which are valuable to a country. They help teach the work ethic. You don't win at chess unless you work at it, but if you do you'll surely win. That's great training for life.

Fear

One thing that's been bugging me is why so few hams have actually tried packet radio. I wonder if it has something to do with fear? A fear of embarrassment of making mistakes when you're into something completely new? A fear of displaying your own ignorance of both radio and computers? A fear of the unknown?

It isn't as if it costs much to get in-

involved with packet radio. And it isn't as if you don't know that there are several thousand hams having a ball with it.

So let's look at this fear thing and see if we can understand it better. People generally fear things they don't understand, right? So let's look at the other side of that coin. Are there any things you understand that you fear? I said fear. I'm not afraid of electricity, I respect it. I've gotten knocked on my kister a couple of times and that's generated a surprising amount of respect. But it's not fear or terror.

Once we take the trouble to find out more about the things that we are afraid of we no longer are afraid. I'm afraid when I'm walking on a New York street at night and a group of black or Hispanic teenagers pass me. I'm afraid because I don't know whether they are dangerous or not. It's the unknown. If I were to take the trouble to get to know them I would no longer be afraid.

The next time fear hits, perhaps you can consider that if you understood what you are afraid of you wouldn't be afraid. So, instead of fearing and probably running away or avoiding, try to find out more about what has frightened you . . . knowing that this will eliminate your fears.

Religions rule billions of lives through fear. Fear of punishment for sins. Fear of the devil, of hellfire, and so on. I can't fault them for that because it pays off. It pays off in billions of dollars. We have some extremely wealthy religions, all built on fear. But you know, we haven't a shred of proof that any of these fears are real. Millions of people believing things doesn't make them true, otherwise the sun would still be spinning around the earth and Columbus would have fallen off the edge of the world.

Now, are you ready to give packet a try? It's wonderful fun and you're missing a whole big piece of our hobby. Yes, of course you're going to have to learn a lot. And you're going to make all kinds of dumb mistakes. Hey, there's always a first, right?

Step two . . . I expect a letter from you thanking me for pushing you into this.

Reason Prevails

The League has backed down on their opposition to automatic relaying on the low bands. I'll let the packeteers give you the gory details on what happened.

I can understand concerns about the blind relaying of messages, where there would be a strong possibility of jamming contacts already in progress. This is much like K1MAN or W1AW coming on their self-assigned frequencies and broadcasting blind.

Most of us pick what sounds like an unused frequency and then ask if anyone is using it before we launch into a long CQ. Perhaps the packet software developers can get our packet (and RTTY) systems to emulate this approach. If a relay station could send a short coded signal which would ask if

Continued on page 66

From the Hamshack

Joel Weder VE6VOX, Calgary, Alberta, Canada I was reading my July/August copy of *The Planetary Report* (published by The Planetary Society, which promotes space exploration) and came across a rather interesting article, "Doing More With Less: The New Way of Exploring the Solar System," by Rex Ridenoure. The article discussed the trend towards smaller and more cost-effective space probes. What's interesting about it for you and me is his description of the rate of technological change involved: "... the SDI and commercial space segments are three to five years ahead of the space exploration field in developing and applying new satellite technology; these groups were preceded by the academic and amateur radio communities."

These days everyone (Wayne especially) seems to be wondering where amateur radio is going—what will be our reason for being. Well, I think this article just shone a little light on the path. There are still hams experimenting at the forefront of technology, whether it be with OSCAR, packet or repeater linking via satellite. The club that I recently joined here in Calgary (CARA) is one of the most progressive I've seen because (it seems to me) they keep politics to a minimum, aren't afraid to jump into a new project and concentrate on getting things done. Those are, as any good businessman knows, among the central keys to success.

I recently gave up a well-paying job as a military photographer to go to college. Most of my friends think I'm crazy to do such a thing during a recession, but when I graduate as a telecom technologist it'll "open a whole new world" to me. I guess my point is that we, as amateurs (and North American society as a whole), need to be willing to take chances on change and innovation. We cannot allow ourselves to continue being afraid of the future.

David K. Hansen KBØEVM, Jeddah, Saudi Arabia Greetings from Jeddah, Saudi Arabia. Amateur radio is pretty limited here, although the Oasis Amateur Radio Club has been in operation since last February. The call is 7Z2AB and our QSL manager is AAØBC. There are about 15 hams on the roster and many activities going on. The equipment includes an ICOM 725; a Kenwood 440S; beams for 12 and 17 meters, and for 10, 15, 20 and 40 meters. Our hours are somewhat limited, but any availability of operation is appreciated. As you can

imagine, we usually get quite a pile-up when we get on the rig.

I have been here for eight years, arriving as a private and commercial pilot ground instructor and have moved to being the senior instructor for 747 avionics systems instruction for the flight crews. My former occupation was as a physics teacher in a high school in Minnesota. Wayne, I do agree with some of your conclusions in your editorials concerning the education of youth. However, it is easy to use a big brush and to think every classroom is the same. There is a lot of quality out there. Granted, there may be less than in previous decades, and the objectives of education may not be appropriate to today's required work force. So, why am I not still in the classroom? I had given a lot of effort to the students, received several awards for teaching excellence, and received little support from the local administration. I did what I wanted to do, did well, but received nothing extra beyond what an "average" teacher would receive. Finally, teaching college placement physics, standard physics, and aerospace; and acting as radio club advisor, chess club advisor, faculty social committee chairman, athletic field manager and science department chairman wiped me out. The number of students increased and the money available for supplies went down. How do you teach physics when the annual money per student for all supplies is less than a meal for two at McDonald's?

Until the business world and the public want to have responsive, quality schools and are willing to support appropriate school goals emotionally and financially, there will be little change. I did get tired of music departments getting personal computers to maintain inventories of instruments, uniforms and candy sales while the science department uses instructor-purchased computers. It was that or have none. But then, music and athletic departments have their parent support groups. Maybe there should have been a science concert some evening.

There will continue to be young dreamer teachers, there will be those who sacrifice their own family time to do a good job, but somewhere around the 30- or 40-somethings they look in the mirror and make some inner comment about "what is this getting me?"

Let me get off the soap box and to the main reason for writing. Being here I can appreciate the restrictions on radio operations. I only hope that amateurs are picking up the baton

and doing something about getting young people interested and upgrading their own skills in a few of the multiple areas of amateur radio. A suggestion I would make is to adopt a library, either a school or public library. Make it a normal practice to donate a book on electronics or amateur radio on each of your birthdays or on July 4th as a birthday gift to the country. Skip that meal out in the restaurant and donate a book instead. Send the XYL a card and tell her that her flowers were converted into a book. Encourage others to do the same.

Fred E. Piering WD9HNU, Maitland FL My God! Wayne, what's this world coming to? Since the birds have left the nest, my wife has contemplated starting a small business, such as a grocery shopping and delivery service for the elderly or infirm (she likes to spend other people's money—read: mine). So, when I read your editorial in the November issue I showed her the section you wrote concerning "Making a Buck." When I found her reading page 76 I inquired, "What are you doing?" She responded that she found you very interesting and profound, very informative!

She asked how long you had been writing editorials and I told her 30+ years that I could remember (I still have some 73s from the beginning). Well, now I am under strict orders that from now on when I receive my 73 in the mail, I am to turn it over to her so she can read your editorials. Maybe she should pay for the next subscription?

L. E. Dickason N8MKM, Jackson OH Wayne, your June editorial requires some comment. I agree that 20 wpm is a little silly in our digital world. I am a Tech with 5 wpm, but I really can't see the value in suffering through the code to upgrade. Why not a series of tests which emphasize theory, rules and COURTESY?

I started reading 73 as an SWL because you had good articles on antennas and other topics and because you didn't talk about SWLs as if they were vermin. It takes more than glossy paper to make a magazine.

Speaking of high-tech, I would like to build a digital signal processor and a panadapter or spectrum analyzer. Where are the projects? I enjoy "Above and Beyond" because it pushes my understanding to the limit. Isn't that what it's all about?

Guy Metrocavich, via Instinet I thought Sheets and Graf's article titled "ATV Transmitter, Part I" (August 1992) was great. I enjoyed the thorough yet concise circuit description. For example, the description of the Q1 oscillator gave me all I needed to understand how it worked.

I have seen this oscillator in cir-

cuits for years and never figured it out. I always looked for feedback from the emitter or collector to the base; I did not realize it was a common base configuration.

The rest of the article was equally insightful. Thank you.

Jim Kocsis WA9PYH, South Bend IN Wayne, I thought I'd better write to you and let you know that I've been taking some (not all!) of your advice. First of all, I'm a subscriber since 1965 so I'm a long-time reader of 73.

Ham radio is alive and well in our town and I'm fairly active, but I thought I would share some info with you and 73's readers on non-ham-radio subjects. I read a lot and have read some very interesting books in the past few years. There are much more interesting things and thoughts going on in the world than what the AP, UPI, etc. think we should know.

Why am I mentioning this in a ham radio magazine? Only to prod people to talk about more interesting things than RST, the rig, weather, QSLs, etc. My gosh, we have a "meeting room" that spans the country (actually the world!) that we can use 24 hours a day for free and we are not doing it! I've tried skipping the rubber-stamp QSO format and have had some excellent discussions with fellow hams. I heavily recommend this to the readers of 73.

As far as TV is concerned, I personally only watch a few shows regularly. I want to be informed or entertained (made to laugh, not depressed!). What can you do in your spare time if you don't want to yak on the air? Anything! But don't waste your time doing the same thing over and over and over again. My gosh, we're not robots (or are some of you?). And if you can't read when there is time (my eyes get tired at night but I still feel like I need some input) there are tapes at your local library that are instructive, entertaining or just pleasing to the mind. Did you ever try listening to one of those subliminal tapes (weight reduction, controlling anger, dealing with angry people—the list is endless)? Did you ever try listening to a tape on self-hypnosis? Or music from another culture? There are tapes that are condensed versions of some very good books.

Now, after you've read something off the beaten path, try telling someone you contact on the air about it and discuss it—you will be pleasantly surprised by their reaction! Ditto for people at work. Mostly what I've heard is: "Gee, I always wanted to know about that . . . but I never had the time."

How about it Wayne, am I right? The most exciting things are the unknown and the new, not the same old same old.

Please keep "on our cases" Wayne, we need the constant motivation!

The Emergency Broadcast System Today

Hearing "this is only a test" broadcast by your local radio station may become a thing of the past. The FCC has announced a "comprehensive attic-to-basement" plan to overhaul the Emergency Broadcast System (EBS). EBS has not been updated since 1976. Its name may be changed to the Emergency Warning System (EWS).

Proposed is a new form of silent testing and a cutback (from weekly to monthly) in the amount of on-air testing. Actually, new equipment will be able to test itself.

The FCC is suggesting a new "subaudible" warning system that will preclude using the familiar 20-second tone that mixes 853 Hz and 960 Hz together in order to activate emergency listening devices.

Cable operators, who currently do not have to perform EBS tests, will be required to join TV and radio broadcasters.

In 1991, EBS was used more than 1,500 times. The Emergency Broadcast System was activated nearly a day before Hurricane Andrew hit the south Florida coast.

EBS was established in 1951 as the CONELRAD (Control of Electromagnetic Radiation) system during the Truman administration to provide the president with the means of addressing the American people in the event of a nuclear attack. The service has yet to be used during a national emergency.

The Truman administration envisioned that the President or a government agency would activate the tone to control a master radio or television station, one specifically constructed to withstand an atomic explosion. The station's command tone would be heard by other stations, linked in a pyramid: Those stations would be heard by other stations, and so on.

Currently, EBS is only used at the local level to notify the public of dangerous conditions: toxic leaks, tornadoes, hurricanes, chemical fires, earthquakes, floods and such. The EBS was even used during the LA riots to call off-duty police officers back to work. *TNX The F.O. Flyer, October 1992.*

Youth Forum Interviewees Needed

Carole Perry WB2MGP is seeking articulate, active amateur radio youngsters up to age 18 to be interviewed for various youth forums across the country.

Please contact Carole at P.O. Box 131646, Staten Island NY 10313-0006, or call her at (718) 983-1416.

Congress Enacts New Restrictive Scanner Law

The law prohibiting the manufacture of scanners with (or easily modifiable to include) the cellular bands passed the Senate (reportedly *without* debate) on October 8th. The "cellular ban" was an amendment to the FCC funding bill and it is entirely possible and even probable that most senators had *no* idea the cellular amendment was there or what it meant. The following comments, which have appeared in several places, are speculation until an official interpretation is published:

(1) Receivers with external converters, lab-type receivers and tunable receivers are *not* affected by this law. *Scanners* are affected. Once the law goes into effect (180 days from October 8, 1992), no scanner can be manufactured that will cover the cellular bands, nor can it be made to be easily modified.

(2) It looks as though as long as the scanner is made with a *continuous* large frequency range, you can include the cellular frequencies.

(3) This law *does not* affect used scanners or scanners that were manufactured prior to the effective date of the law.

Here is the exact text of the new law:

Sec. 408. INTERCEPTION OF CELLULAR TELECOMMUNICATIONS.

(a) **AMENDMENT**—Section 302 of the Communications Act of 1934 (47 U.S.C.) is amended by adding at the end the following new subsection:

(d)(1) *Within 180 days after the date of enactment of this subsection, The Commission shall prescribe and make effective regulations denying equipment authorization (under Part 15 of Title 47, Code of Federal Regulations, or any other part of that title) for any scanning receiver that is capable of—*

(A) *receiving transmissions in the frequencies allocated to the domestic cellular radio telecommunications service,*

(B) *readily being altered by the user to receive transmissions in such frequencies, or*

(C) *being equipped with decoders that convert digital cellular transmissions to analog voice audio.*

(2) *Beginning 1 year after the effective date of the regulations adopted pursuant to paragraph (1), no receiver having the*

capabilities described in subparagraph (A), (B), or (C) of paragraph (1), as such capabilities are defined in such regulations, shall be manufactured in the United States or imported for use in the United States.

[By Roy J. Cloutier, adapted from public postings on Prodigy. *TNX Westlink Report #637, November 12, 1992.*]

Space Symposium a Great Success!

The Tenth Annual AMSAT-NA Space Symposium and meeting was held at the beautiful Intelsat Headquarters building in Washington, DC, on October 9-11. The 300 in attendance heard presentations on such diverse subjects as antenna testing for the Phase-3D spacecraft, use of the PACSATs, SAREX hardware configurations and the AMSAT awards program. Once again this year, the ARRL co-sponsored an educational workshop at the Symposium. A complete satellite station that was installed for the weekend was used to make several AO-10 and AO-13 contacts, including a scheduled QSO with a special event station at the AMSAT-Denmark meeting being held in Copenhagen.

Dr. Ron Parise WA4SIR was the banquet speaker. He entertained the audience with a talk, slides, and a movie detailing the Astro-1 space shuttle mission on which he was a payload specialist and SAREX operator. The evening ended with presentations of awards and a drawing for the numerous door prizes that were generously donated by many different companies.

The printed proceedings (32 papers, almost 300 pages total) are available from AMSAT-NA Headquarters. Look for a detailed report on the meeting and symposium in the next issue of the *AMSAT Journal*. *TNX AMSAT-NA; Westlink Report #637, November 12, 1992.*

The Techno-Whizzy 1, Part II

Build a direct digital synthesis (DDS) transmitter.

by John Welch N9JZW

In Part I of this article, we built the VFO, frequency selector and power supply boards. Using just these, you have a very QRP transmitter (2 milliwatts) or a nice signal generator. For those who like a transmitter with a little more oomph, here's the amplifier stage.

Since we've gone through a lot of trouble and expense to generate nice, clean, pure sine waves, it would be a real waste to run it through a class-C amplifier. Class C would also require a filter for every band or two, complicating things even more. Class A is the right approach (with the added benefit that when we make the TW-1 do SSB we won't need a new amp).

Designing a class-A power amplifier wasn't easy (digital likes me; analog hates me). The amplifier was designed to be easy-to-build, requiring no adjustments. It is not, however, the most efficient or powerful design. The amplifier will remain linear down to about 10 volts, and remain within maximum specs up to 13 volts. It is designed to run from a freshly-charged 12-volt battery or 13.8-volt power supply. More than 13.8 volts won't give you more power—it will just burn up the final amp!

Class A has its drawbacks—namely, it consumes more power than class C and consequently also runs hotter than class C. I've sidestepped this issue by keying power to both the driver and the final stage, so it will only consume that power and generate that heat while you have the key down. This also sidesteps another common problem—stray RF getting into the final and being amplified to a low-level signal.

Theory of Operation

The RF signal at about 1.5-2 mW comes into the base of Q2 at J2. Resistors R5, R3 and the transistor combine to present a 50-ohm load to the input. Emitter resistors R6 and R7 keep the driver Q2 stable, limit current flow and, combined with bypass cap C3, provide some frequency-dependent output compensation. The output runs through C2 to a 4:1 step-down transformer, T1. This transforms the 50-ohm output to a 12.5-ohm input to the final amplifier. C10 keeps the DC bias provided to Q3 by R6 and R9 isolated from the transformer.

Photo A. The front panel of the Techno-Whizzy 1 DDS transmitter.

Photo B. Close-up view of the power amplifier module.

Photo C. Hooking up all of the modules together to complete the Techno-Whizzy 1.

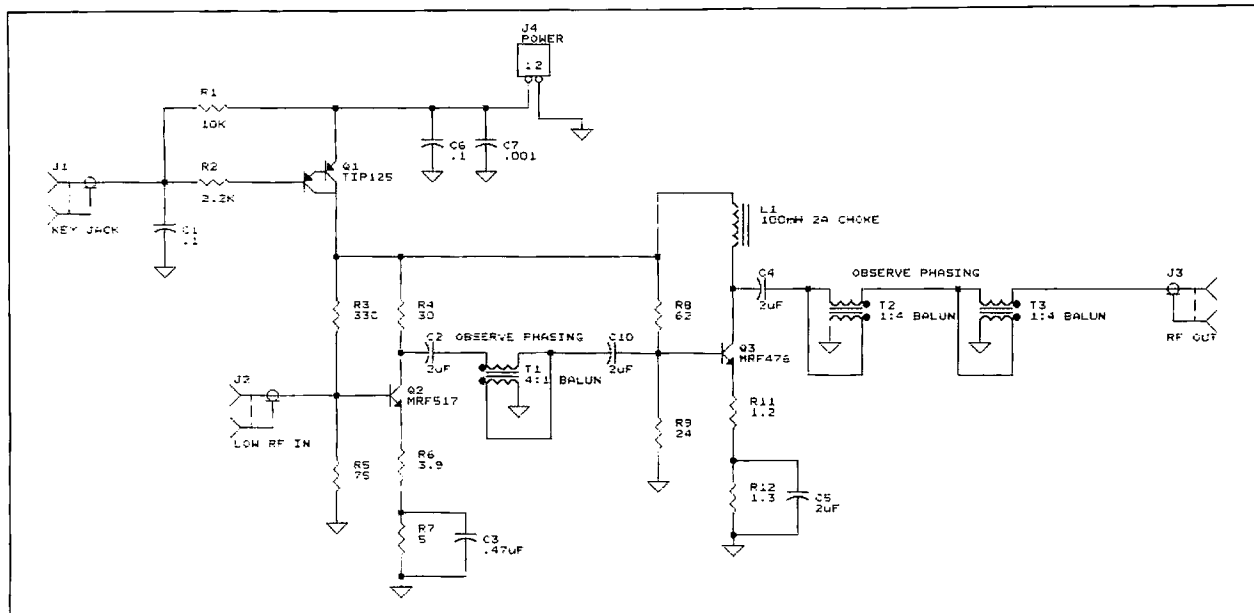

Figure 1. Schematic diagram of the power amplifier board.

Choke L1 provides power to the final amplifier, Q3. Emitter resistors R11 and R12 keep the final stable and provide limited output compensation with C5. The output flows through C4, into the 16:1 matching network of T2 and T3, then to the antenna connection at J3.

Power comes into the keying circuit through J4, the Transmit/Receive switch on the front panel. Capacitors C6 and C7 bypass RF to ground. The key is connected to jack J1. The unit is keyed by grounding Q1 through R2. R2 and C1 help in shaping the keying waveform, preventing sharp edges. Power to both the driver and final is keyed, keeping the power drain and associated heat to a minimum.

Construction

The amplifier board should deliver about a watt of clean signal into a 50-ohm load. To do so will require you to wind some balun cores into transformers. There are three on this board, all 4:1 baluns using BN-43-202 cores. Winding them is a lot easier than explaining how, so take courage.

To wind the transformers, take about six feet of 30-gauge magnet wire and fold it in half. Putting one end in a vise, twist the wire to about 15 turns per inch (I used an electric screwdriver for this and it went very quickly). Wind this twisted wire up through the left hole of the balun core and back through the right. That's one turn. Go back in through the right and back out through the left, for two turns. Continue, winding eight to 12 turns on the core, leaving wires coming out of each hole at the bottom. Now cut the folded-over tip in the middle, making it two wires wrapped around each other.

Scrape back some insulation on the ends of the wire and use an ohmmeter as a continuity tester to identify the two wires. Twist the left-hand side of wire #1 to the right-

hand side of wire #2. The left-hand side of wire #2 will go to ground, and the signal goes between the twist and the right-hand side of wire #1.

Now that you've got the transformers wound, install T1 on the board. Orient it so that the twisted end is in the middle, and one wire goes to ground and the other wire goes to Q2 (on the board, the "twisted" end is the two holes that are shorted together). This steps the 50-ohm output of Q2 down to 12.5 ohms into Q3.

Install the other two baluns at T2 and T3. Here again the twisted ends go in the middle, with one wire to ground and the other wire towards the output. These provide a 16:1 step up from the 3.125-ohm output at Q3 to 50 ohms at the antenna jack.

J1 is the input from your key. Hook this to a jack with a chunk of two-conductor wire or RG174 coax. J4 is the 12-volt power input. Hook this to a power input jack (if fused, use a 2-amp fuse). J2 is the RF output—attach this to the output jack (SO-239 preferred) with some more RG174. J3 is the RF input from the DDS

Figure 2 (a). PC board foil pattern of the power amplifier board. (b). Parts placement.

VFO board—leave this vacant for now.

SW1 switches power from receive to transmit. As the amplifiers are class A, they consume a lot of power just sitting there. Leaving this stage powered down while receiving will cut the TW-1's power consumption to a trickle.

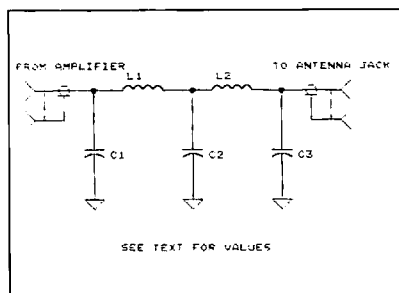

Figure 3. Schematic diagram of the optional output filter board.

Install the transistors next, matching the shapes to the shapes on the board to assure proper pin arrangement. Q1, the TIP125, shouldn't need any heat sink, but Q2 (an MRF517 or 2N3866) will—a top-hat type will be adequate. The MRF476, Q3, also needs to be heat-sinked, preferably to the back panel of the radio. Be sure to use thermal goop, a mica insulator and a nylon screw to attach this transistor to the case. For testing, you can use thermal goop and a TO220 heat sink, but don't run it for long!

By now you're almost done. Just install the rest of the parts. They're all passive components so there is no "backwards"—but be sure to get them in the right spots! As always, double-check your work.

Attach a dummy load (50 ohms 5 or more watts will work fine) to the SO-239 RF output connector. Turn SW1 to "transmit" to apply 12 volts to J4. Attach your voltmeter to the "hot" end of R5. With the key jack open, you shouldn't read more than 0.1 volt. With the key jack shorted, you should read around 2 volts. A small difference is

25	3	T1,T2,T3	4:1 balun on BN-43-202 core

Note: A complete kit of parts (including the PC boards) is available from Elkronics Northeast, Rt. 1 Box 789, Hancock NH 03449. Phone: (603) 525-4001. Prices as follows: DDS VFO module — \$99; Diode Matrix module — \$49; Power Amplifier module — \$49; Output Filter module (specify band) — \$10; A complete package of all modules — \$199. The Qualcomm Q2220 DDS chip can be ordered separately for \$39. All prices include postage.

Etched and drilled PC boards for this project are also available separately from FAR Circuits, 18N640 Field Court, Dundee IL 60118. Pricing: DDS VFO PC board — \$8; Diode Matrix PC board — \$8; Power Amplifier board — \$6; Output Filter — \$3. Please add \$1.50 per order.

The Q2220 (as well as data sheets) is available directly from Qualcomm, 10555 Sorrento Valley Rd., San Diego CA 92121; (619) 597-5005. The price is \$49 (1-24 qty.); \$150 minimum order.

The CA3338A, the 55 MHz clock oscillator and most of the small parts are available from Digi-Key; (800) 344-4539.

Toroids are available from KA7QJY Components (Danny Stevig), Box 3893, Logan UT 84323; Tel: (801) 563-5173.

Programmable-Frequency Audio Generator

High accuracy with digital control.

by Loyd W. Redman

Most audio signal generators built around IC timers or op amp oscillators require some external capacitors and resistors to determine oscillator frequency. To obtain high accuracy of an output frequency, the external capacitors need to be adjustable. If the oscillator is to have several frequency ranges, you'll need several external capacitors in addition to trimmers for fine frequency adjustments. Some capacitors change value with aging, so manual adjustments must be made each time the generator is used.

Digital Audio Frequency Control

Micro Linear makes the ML2035 and the ML2036 IC sine wave generators needing

only one external component, a crystal. The frequency is digitally controlled, so no external capacitors need to be adjusted to change frequency ranges or to fine-tune a selected frequency. Figure 1 shows the schematic of a programmable-frequency audio generator using either the ML2035 or the ML2036 ICs.

The heart of both the ML2035 and the ML2036 is a DAC (digital-to-analog converter). We enter a 16-bit digital word serially and get a sine wave output. Refer to Figure 2 and we'll review the operation of a simple DAC. The output directly from our basic DAC is not a nice smooth sine wave, but a triangle wave. The triangle wave is ac-

tually a series of voltage steps, not the smooth waveform we would see when an oscillator output is derived from the voltage at a capacitor terminal.

Here's how the voltage steps are generated. The circuit of Figure 2 can be viewed as an operational amplifier wired as an inverter, with separate digitally selectable input resistors. The voltage gain equation for an inverting op amp is: $A = R_f/R_{in}$. Our switches are SPST electronically controlled, solid-state switches. Suppose the digital control word contains four bits. We then have 16 possible output voltage steps. When the digital word is 0001, S4 is closed, connecting +10V to

Continued on page 18

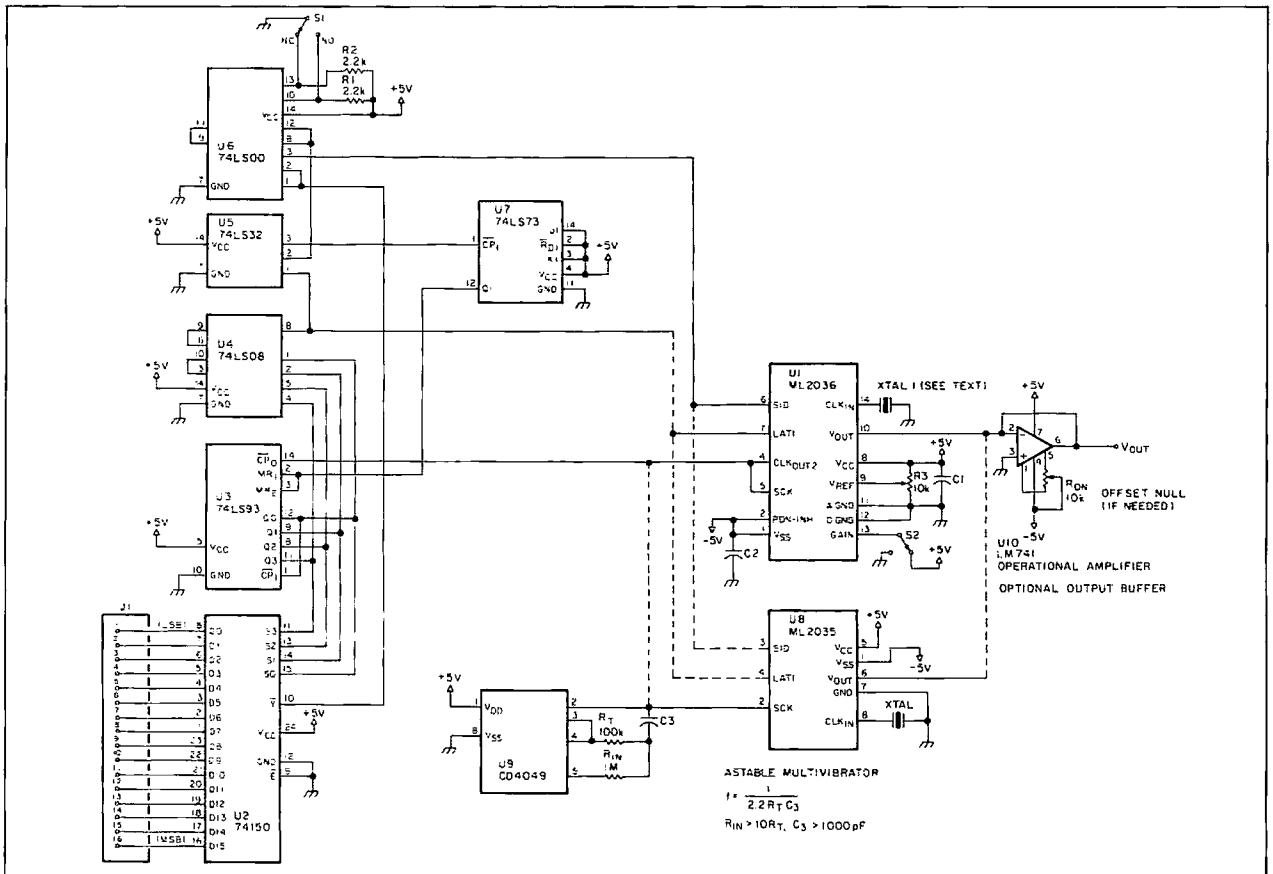

Figure 1. Programmable-frequency audio generator circuit diagram using the ML2036 or the ML2035. Dashed lines indicate changes in wiring when using the ML2035.

Programmable-Frequency Audio Generator *Continued from page 16*

the end of the appropriate resistor in the network so the gain of U1, R_f/R_{in} , becomes $1/16$ or 0.0625 . The output voltage will be $0.0625 \times 10V$ or $0.625V$. Thus, the second output voltage step will be $1/16$ of the reference voltage. If our up-counter begins at 0000, the 10V reference is not connected to U1, so the first voltage step is 0V. Our word generator continues to enter digital words in sequence to 1111. At a count of 1111, switches S1-S4 are closed, connecting resistors in the network to produce an amplifier gain of 0.9375 and an output voltage of $9.375V$, $15/16$ of the reference voltage.

At this point you may ask, "Where's the rest of the triangle wave?" With digital control words of 0000 to 1111, our output is only one quadrant of the triangle wave. Our control logic now directs the word generator to count down in the sequence 1111 to 0000. This will get our output steps back to 0V. Now we need to generate the negative-going half of the triangle wave. The sign bit from our word generator causes the control logic to change the position of S5, disconnecting the input to U2. The word generator counts up, then down, producing the negative-going alternation of our triangle wave.

If we apply an 8-bit digital control word and modify our switches and input resistors, we can produce an output voltage of 128 (2^7) steps. The 8th bit is used as the sign bit. We observe that the more voltage steps we have, the nearer the output of our DAC resembles a true triangle wave.

We could use a triangle wave as an audio test signal but the results wouldn't be as satisfactory as if we had used a true sine wave. Figure 3 shows a comparison of amplitudes between a triangle wave and a sine wave, one quadrant only. You can see that at an angle of about 55 degrees, the difference in amplitude between the two signals is about 2V.

The ML2035 and the ML2036 add two important blocks to our basic DAC that give us a near-ideal sine wave output. (Detailed spec sheets are available from Micro Linear, 2092 Concourse Drive, San Jose CA 95131.) The first of these functions is a sine look-up table. Remember back before the advent of hand-held calculators, when your math text contained tables of sine values for angles 0 degrees to 90 degrees? The sine look-up table is in the form of a read-only memory (ROM). The instantaneous value of the output voltage is derived from the value of the sine of an angle that is a multiple of $90/128$, or about 0.703 degree. The output waveform is still a series of voltage steps. You can observe these steps with your 'scope if you operate the circuits with a clock input much slower than the recommended minimum of 3 MHz.

The second added block in our circuit appears just before the output. This block is a low-pass (smoothing) filter. Many of the internal functions of the ML2035 and the

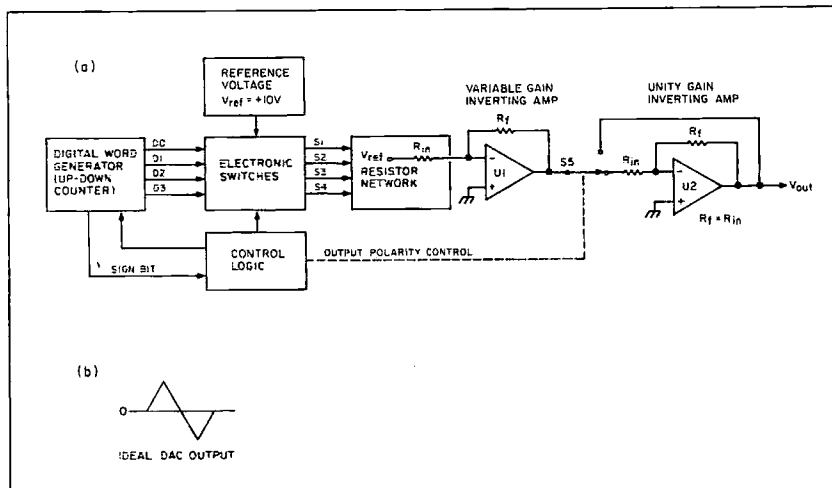

Figure 2. Block diagram of a basic digital-to-analog converter (DAC).

ML2036 operate at $1/4$ clock frequency, 750 kHz, if our crystal is 3 MHz. Since we're interested in frequencies of 20 kHz or less, the low-pass filter removes most components of the higher frequency that are "straying" around in the close confines of our integrated circuits.

How the Circuit Works

At initial power on, our circuit does nothing and we observe these conditions: The Q1 output of U7, a J-K flip-flop, is high. This high, connected to the master reset pins of U3, a 74LS93 4-bit binary counter, causes all the outputs of the counter to be low, 0000. With the master reset pins high, count is inhibited even though the 74LS93 is being clocked by the pulse train from pin 4 of the ML2036. The CLKout2 signal frequency is $1/8$ our crystal frequency.

After we apply the 16-bit word to J1, circuit action is started by depressing and releasing S1. This sends a momentary high to one input of U5, a quad two-input OR gate, bringing pin 3 of U5 high, toggling U7. The Q1 output of U7 connected to the master reset pins of our counter goes low, enabling the 74LS93 to start counting.

Now that we have the circuit action start-

Figure 3. Comparison of one-quadrant output voltages from a DAC.

ed, we'll describe how we use the ML2036 since it has several features that the ML2035 does not have. The two main support circuits for the sine wave generator are U2, a 16-input multiplexer, and U3, a 4-bit binary counter. The frequency of the sine wave out of the ML2036 is determined by a 16-bit digital word serially clocked into pin 6, SID (serial input data).

The magnitude of this 16-bit value is determined by the equation: $n(10) = (f_{out} \times 2^{23}) / (f_{CLKin})$. If we use a 3 MHz crystal, this equation becomes: $n(10) =$

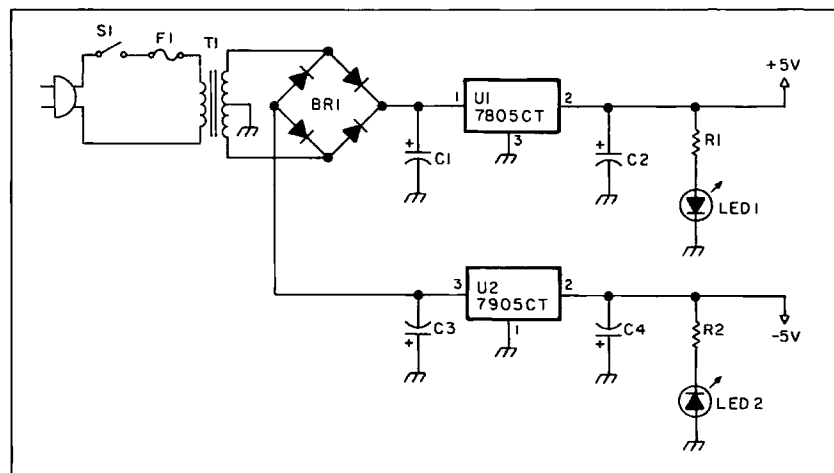

Figure 4. Schematic diagram of the +/- 5 volt power supply.

Figure 5. PC board foil pattern for the Audio Generator.

$(8,388,608 \times \text{fout}) / 3,000,000 = 2.7962 \times \text{fout}$. This gives a decimal (base 10) number which must be changed to digital (binary) form. The circuit builder has a variety of methods to apply the digital word to J1 and subsequently to the inputs of the 74150; 16 SPDT switches, 16 DIP switches, or a 16-key keypad encoder. The 74150 can be visualized as a 16-position rotary switch. When started, the 74LS93 counter counts 0000-to-1111, selecting in turn each of the 16 inputs to the multiplexer, LSB (least significant bit) first.

Since the output of the multiplexer is the inverted form of the input bit, we route the inverted bits through one gate of U6, a quad, two-input NAND gate, on to the SID (serial data) input of the ML2036. Each of the 16 bits must be individually clocked into the ML2036 before the 74150 switches to the next bit. Pin 4 of the ML2036 gives us a pulse train at frequency of CLKIN/8. We use

these pulses to clock the counter (on the high-to-low transition). Note that the CLKIN/8 signal is also connected to the pin 5, SCK (serial clock) input. The rising edge of this signal clocks in the bit selected by the multiplexer. After the 74LS93 has counted to 1111, clocking in all the 16 bits, the entire word must be latched by a falling edge applied to pin 7, LATI (serial latch). This falling edge latch signal is derived by feeding the counter outputs to two gates of U4, a 74LS08 quad two-input AND gate. The 74LS08 serves effectively as a four-input AND gate. Until the 74LS93 count reaches 1111, pin 8 of the 74LS08 is low. When pin 8 goes high at count 1111, pin 7 of the ML2036 goes high. This high is also fed to a gate of U5, a 74LS32 quad two-input OR gate. Pin 3 of the 74LS32 goes high, "toggling" U7, a 74LS73 J-K flip-flop. The Q1 output of the 74LS73 is connected to the master reset inputs of the counter, bringing

them high and clearing the counter outputs to 0000. As long as the master reset inputs are high, the counter will not count. With all the counter outputs at 0000, pin 8 of our 74LS08, and subsequently the signal at the LATI input to the ML2036, go low, latching in the 16-bit word. At this latching, the sine wave output appears at pin 10 of the ML2036.

Figure 1 shows our ML2036 with all the bells and whistles attached. S2 provides a logic high or low to pin 13, the GAIN input. When pin 13 is high, the output sine wave peak amplitude is plus or minus VREF. When pin 13 is low, the peak output amplitude is plus or minus VREF/2. R3 provides a variable voltage at pin 9, VREF. If a variable VREF is not desired, we tie pin 9 directly to +5V. Our circuit shows pin 2, PDN-INH (power down-inhibit), tied directly to -5V. [Ed. Note: You can use the +/- 5 volt supply shown in Figure 4 to power the Audio Generator.] In this configuration, when we want the ML2036 to stop generating an output, we simply shift in a 16-bit word of all zeros.

The dashed lines in Figure 1 show the modifications to the circuit when the ML2035 is used. The main difference between the two circuits is that we use a CMOS hex inverter wired as an astable multivibrator to furnish a clock input to the 74LS93 and the serial clock signal to pin 2 of the ML2035.

The circuit builder can't go wrong by including an external buffer at the output of either circuit. The specified output drive capability is a 1k, 100 pF load. I used the ML2036 output directly into the auxiliary input of an audio tape recorder with satisfactory results. I used a 0.5V p-p sine wave, amplitude adjusted with R3. The LM741 operational amplifier makes a suitable output buffer for audio frequencies.

Construction

Construction methods are the circuit builder's choice. I assembled the circuit temporarily on modular breadboard sockets similar to Radio Shack 276-174. I use 22-gauge jumper wires between IC pins. After building the circuit and verifying operation, I then make a permanent assembly on Radio Shack's matching PC board, 276-170. I prefer to use wire-wrap for final connections. Refer to the master wire list and use a continuity checker to verify correct wiring before installing the ICs. Lead dress does not appear to be critical. In the temporary version of the circuit, I used a 12 MHz crystal with untrimmed (1-1/2") leads and connected the CLKOUT pin (6 MHz) to the 74LS93. However, the crystal should be placed physically as close as possible to the CLK in pin. Unless your power supply is on the same PC board as the rest of the circuit, you should bypass the +5V and -5V connections to the ML2036 with 0.1 µF ceramic disc capacitors. [Ed. Note: PC boards are available for the Audio Generator and the +/- 5 volt supply board (see the Parts List for details).]

Figure 7. PC board foil pattern for the +/- 5 volt power supply.

Figure 8. Parts placement for the power supply.

Checkout

The minimum requirement of instruments needed for checkout is a logic probe or DC voltmeter, and some form of a simple audio amplifier. If you want to go first class you can also use a scope and frequency counter.

This checkout procedure applies to the ML2036-based circuit. First, open the short between pin 4 and 5 of the ML2036. Then open the lead between pin 4 of the ML2036 and pin 14 of the 74LS93. Next, connect a

ML2036. Now turn on the power and apply a 16-bit word to the 74150. If you're using an audio amplifier to verify the sine wave generator operation, select a 16-bit word to produce a frequency you can hear.

Depress and release S1 to "toggle" flip-flop U7 and enable the 74LS93. You will observe that all the LEDs are off, indicating a count of 0000 which shows us that switch position 0 (LSB) of the 74150 is selected. Now depress the bounceless push-button

Parts List

Audio Generator

U1	ML2036 programmable sine wave generator
U2	74150 16-input multiplexer
U3	74LS93 4-bit binary ripple counter
U4	74LS08 quad, 2-input AND gate
U5	74LS32 quad, 2-input OR gate
U6	74LS00 quad, 2-input NAND gate
U7	74LS73 dual JK flip-flop
U8	ML2035 programmable sinewave generator
U9	CD4049 hex inverting buffer
Y1	Crystal 3 MHz to 12.4 MHz (see text)
R1,R2	2.2k, 1/4 W, 5%
R3	10k potentiometer
RT	(see text)
Rin	(see text)
C1,C2	0.1 μ F ceramic-disc capacitor
C3	(see freq. equation for U9)
S1	SPDT momentary switch
S2	SPDT switch
PC board	See Note 2
Misc:	Perfboard materials, IC sockets, wire, solder, enclosure, hardware, etc.

Power supply parts list.

S1	SPST switch, 6A @ 125V	RS# 275-634
F1	Fuse, fast acting, 500 mA	RS# 270-1271
T1	Power transformer, 12.6 VCT, 450 mA	RS# 273-1365
BR1	Bridge rectifier 1A @ 50 PIV	RS# 276-1161 or 276-1146
U1	7805CT, +5V voltage regulator	RS# 276-1770
U2	7905CT, -5V voltage regulator	(See Note 1)
C1,C3	2200 μ F/35V electrolytic capacitor	RS#272-1020
C2	0.1 μ F/35V tantalum capacitor	RS# 272-1432
C4	1.0 μ F/35V tantalum capacitor	RS# 272-1434
R1,R2	330 ohm carbon film resistors, 1/4W, 5%	RS# 271-1315
LED1,LED2	Light emitting diodes	RS#276-041
PC board	See Note 1	

Note 1: The 7905 type -5 volt regulator is not normally stocked by Radio Shack but can be special ordered from them. It's also generally stocked by most mail order houses.

Note 2: Etched and drilled PC boards are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118. The Audio Generator board is \$6 and the +/- 5 volt power supply board is \$5. Please add \$1.50 per order for postage.

Note 3: Micro Linear spec sheets and a distributor list are available from Micro Linear, 2092 Concourse Drive, San Jose CA 95131. Phone: (408) 433-5200. Three of the distributors are:

Tempe Insight Electronics, Inc.	Interface Electronics Corp.	Pioneer Technology
1515 W. University Drive, Suite 103	228 South Street	9100 Gaither Road
Tempe AZ 85281	Hopkinton MA 01748	Gaithersburg MD 20877
(800) 677-7716	(800) 632-7792	(800) 227-1693

330 ohm current limiting resistor and a LED to each of the four 74LS93 outputs Q0-Q3. The anode of each LED is connected to the resistor and the cathode is connected to ground.

Fabricate a bounceless push-button switch similar to S1 in our complete circuit. Connect the momentary switch and resistors so the output goes low-to-high when the switch is depressed. Connect the output of this switch to pin 14 of the 74LS93 and pin 5 of the

you have connected to pin 14 of the 74LS93. The low-to-high transition of the output will clock in the LSB of our 16-bit word. When you release the bounceless push-button, the high-to-low transition of the output will clock the 74LS93 and the LEDs will indicate a count of 0001. Continue operating the switch until you observe the LEDs indicate a count of 1111. Depressing the push-button one more time will clock in the MSB (most significant bit) and releasing it will cause the 74LS93 count to show 0000, bringing the reset inputs high and latching in the 16-bit word. The ML2036 should now be generating the desired frequency.

After you have verified proper operation of the circuit, disconnect the LEDs and current-limiting resistors. Disconnect your temporary push-button switch and replace the short between pins 4 and 5 of the ML2036. Finally, replace the connection between pin 4 of the ML2036 and pin 14 of U3. Your circuit is now ready to be used as an audio frequency test generator.

See Table 1 on page 30

The SP-1 Transceiver

Build the HF "Spider."

by Mike Agsten WA8TXT

The idea of bringing ham radio along on a wilderness jaunt has strong initial appeal, but when the details are itemized it becomes apparent that sheer weight and volume will displace the truly essential needs like drinking water, food, and raiment.

Let's see . . . I'll take the back-up transceiver, deep-cycle trolling battery, wattmeter, antenna tuner, memory keyer, headphones, wire, coax cable . . . wait a minute! Is this Field Day, or a camping trip?

While I don't mind exposing myself to the great outdoors, even the back-up transceiver has considerable monetary value (and weighs a ton!). No; what I need is a rough-and-ready rig. Something so inexpensive that it could almost be considered a "throwaway."

The "Spider" Solution

The SP-1 Spider is designed to fit this bill. I've nicknamed it after our friend the arachnid because, in ordinary operation, you plug in a crystal and wait, patiently if necessary, for your next victim to arrive on frequency! For wilderness skeds, the gang back home is well accustomed to digging weak signals from the noise, but in case they've exaggerated their radio prowess, I've allowed one full watt of transmitter power: perfect for a battery of "AA" cells. At home they can adjust power as needed, so the SP-1 receiver section is nothing special: a direct-conversion mixer and IC audio amplifier. Provision for an audio bandpass filter is included.

A well-designed VFO may be drift-free at home, but in the ever-changing outdoors, crystals are far more predictable, especially in this category of simple equipment. As presented, the Spider holds two switch-selectable FT-243 type crystals, though other arrangements are possible. A single HC-18 wire-lead crystal, for example, can be installed directly on the PC board, or a rotary-switched bank of them might replace the octal socket used here.

It's a bit preposterous to carry accessories bigger than the rig itself, so I've included a built-in telegraph key and, instead of visual output indication, a "smart-tone." This circuit monitors RF output and varies the sending sidetone pitch accordingly. You can be sure you're on the air if you hear "good tone" when you close the key, so leave the wattmeter at home!

Portable operation isn't the only possibility for this rig. It should work even better with the well-deployed sky hooks in your back yard. And if you find a prospective Novice interested in telegraphy, it might make a great loaner. Disable the transmitter and you've got, essentially, a code practice set with a built-in receiver.

Photo A. The SP-1 portable CW transceiver.

Circuit Description

If you judge a circuit's simplicity by transistor count alone, the SP-1 may appear more complex than necessary to fill the needs listed here. But, most generic transistors cost little more than capacitors so I tend to use them with impunity wherever the need to "transfer resistance" occurs, and let the chips fall where they may. Q3 (see Figure 1) is one example of this approach. It's not essential but it does allow you to operate oscillator Q1 at reduced current drain during receive (a battery-saving feature) without sacrificing drive to final amplifier Q2 on transmit. During receive, Q4 prevents the emitter-base junction of Q2 from otherwise clipping the oscillator waveform, which may lead to undesired receiver responses. It also provides a handy place for leading-edge envelope shaping with R9, R10 and C8.

During receive, incoming signals pass through L3, L2, C15 and C19 to receiver-tuned circuit T2/C25 and gate 1 of mixer Q7. With the oscillator signal via C18 present at gate 2, Q7 produces the desired audio beat note which proceeds through volume control R31 to audio amplifier U1. This LM386 IC provides enough power gain to drive a small loudspeaker at home, or ear buds or headphones in the field. Should you desire an audio bandpass filter, insert it in place of wire jumper W3. Receiver fine-tuning is accomplished by varying the tuning voltage on D1 with R1T control R32.

Automatic T/R switching (QSK) begins at key closure. Q8 switches on, rapidly energizing the 12T bus. 12T, the master control signal in this rig, switches many circuits. Let's take a

look at each, in case you need to troubleshoot. D4, via R11, turns on to protect the receiver input. Q5 turns on and, by grounding D1 tuning voltage, frequency shifts oscillator Q1 down about 1 kHz, the actual amount depending on band and L1 inductance.

Q6 mutes the receiver audio while sidetone from Q9 and level adjustment R22 takes over the audio channel. Q4 turns on and keys RF power amplifier Q2. Transmitter RF is routed through low-pass filter L2/L3 to the antenna terminal, and via C16 to RF detector D3. The output level detected by D3 controls Q10 conduction which, in turn, varies the program voltage to Q9, with a programmable unijunction transistor used here to generate sidetone. Full RF output cuts off Q10, raising Q9's program voltage and lowering its output frequency to the normal pitch. This "smart-tone" action is far from linear but still very useful. A dying battery, for instance, will produce a rising sidetone pitch when the key is held down (time to revert to smoke signals or a message in a bottle!). Upon key release, C27 shapes the trailing edge and Q6 with C20 covers up the receive-recovery pop.

Construction

In the top view photograph of the Spider, you can see the octal crystal socket in the left-rear corner. Crystal select switch S2 is just in front. TB1, a four-lug terminal board, mounts along the rear of the top panel. Its terminals are numbered 1 to 4, going from left to right. Connections are DC power to 1 (+) and 2 (-) and antenna system to 3 (ground) and 4 (hot). Along the right edge are 3.5 mm jacks for

speaker/phones (J2-rear) and an external telegraph key (J1-front).

The built-in telegraph key is just left of the jacks. The key arm, a strip of 0.032" brass or aluminum, is mounted on 1/4" spacers and grounded to the top panel by its two mounting

screws. The key knob, a cannibalized equipment foot, is fitted or glued to a hex nut (or two) attached with a machine screw through the arm. The key contact beneath the arm is a 6-32 brass machine screw with the head filed flat. This screw is insulated from the top panel

with a shoulder washer above and a fiber washer below.

The two knobs front and center on the top panel are volume control R31 on the right and receiver incremental tuning (RIT) R32 on the left. Just left of RIT is slide switch S3, unused

here but intended for future audio filter switching or other contingencies. Left of S3, in the left-front corner, is DC power control switch S1.

Nearly all parts reside on the PC board depicted by the etching pattern shown in Figure 2 and the parts overlay, Figure 3. Band-sensitive part values are listed in Table 1. PC boards and project kits for the Spider are available (see the Parts List). The finished PC board is first wired to all the top panel parts except the antenna and ground lugs of TB1 (lugs 4 and 3 respectively) and the common terminals of crystal select switch S2. The board is then hinged over, to be suspended below the top panel (parts down) on 5/8-inch metal spacers. Now the short RF connections to TB1 and S2 can be made.

Overall, this packaging method is economical and makes servicing a snap. Metal work is confined to just one flat panel. Except for TB1 and the key contact, all the innards can be removed intact should you desire to paint and letter the top panel. The case is a Radio Shack No. 270-627 measuring 6.25" x 3.75" x 2" and the finished weight of the SP-1, with two crystals plugged in, is 11 ounces.

I'd be remiss if I failed to mention a lucky coincidence. The entire Spider will nestle into a plastic card file box, with ample room below for the battery pack. Post sked details and secure "ear buds" fit inside the top cover for the ultimate find-in-the-dark convenience. Close the lid and crystals and operating controls are no longer exposed and vulnerable to the rigors of your march. The card file box is a Sterling Plastics No. 529. I use them for QSL storage and see them in the office supply section of stores everywhere. Now at least the radio will survive.

Tune-Up

Connect 12-14 VDC and wattmeter with dummy load to TB1 as described earlier. I recommend a lower than normal (0.5 amp) in-line fuse at first, to minimize damage in case of a major wiring error or soldering mistake. Switch on and close the key. You should hear high-pitched sidetone in the speaker or phones. Install a crystal for the band of choice and increase the fuse rating to 1 or 2 amps (if it hasn't blown!). Close the key and adjust T1 for

Note: PC boards and project kits for the SP-1 "Spider" are available from Lectrokit, 401W. Bogart Rd., Sandusky OH 44870 (no telephone). SP-1BBM, \$12, includes bare PC board and step-by-step construction manual. SP-1PCK, \$29, includes SP-1BBM plus all PC board parts, including those necessary for 80, 40 and 30 meter operation. SP-1KIT, \$39, is the complete kit containing all the above plus case and case parts, but not operating crystals. Include \$4 shipping and handling for SP-1PCK and SP-1KIT orders; the SP-1BBM is postpaid, USA. Ohio residents please add appropriate sales tax. Order direct or send an SASE for current details. This pricing is valid within six months of publication.

The SP-1 Transceiver

Continued from page 29

minimize it at the expense of some "in-band" sensitivity.

On the Air

With the Spider's rather broad selectivity, it may not be obvious if the signals heard are close enough to your frequency for a QSO. Those that approach zero-beat with the RIT control fully counterclockwise are very close. Others may be workable if the operator tunes around for your signal.

In addition to maintaining short-haul skeds from the field (see the sidebar), I had anticipated months of fun trying to extend Spider DX on all three bands from my home QTH. But

right off the bat, 40 meters produced KBØIZC in Kansas, followed by a couple of West Coast stations. Maybe 80 would be less fruitful . . . no. With the rig still clip-led together on the bench, VE7WIN in Coquitlam, B.C., fell right into my lap (er, web!). Further down the log, I see (and well recall) a 559 report on 30 meters from VK2VA in Sydney, Australia. In all cases, the antenna used was my old reliable, a 45- by 70-foot inverted L. So, this rig is indeed adequate, despite its simplicity and low cost. But the results are, more often than not, a tribute to the forgiving nature of HF radiotelegraphy and, occasionally, bull-dog tenacity at the other end. Good luck with the SP-1 Spider!

My thanks to Jim NZ8B, who suggested "smart-tone" and assisted with SP-1 field trials.

Spider in the Field

Sure, the Spider's cute, but is it really practical? We decided to test it in a worst-case scenario on 80 meters. My brother Jim NZ8B grabbed some camping gear, the 80M SP-1 prototype, 65 feet of wire and a 12-volt lantern battery and headed for the hills near Athens, Ohio, about 175 miles distant. Just prior to his departure, we did a quick dial calibration check noting the precise transmission frequency of his main and back-up crystals.

We chose 7:30 p.m. for our nightly schedule time, hoping to catch the window between D-layer breakup and QRN/QRM build-up. With two exceptions, this schedule was maintained for the next 16 days as Jim moved around sampling the camping and hiking fare at various locations. One sked was missed due to freezing temperatures (no antenna at the motel refuge) and another because of a thunderstorm on my end. Otherwise, Spider signals ranged from RST 339 to 569. This was good enough for our brief exchanges but not always armchair copy. With 100 watts going his way, I had no trouble breaking him (QSK) for fills or to mark time during a deep fade. Jim also carried a 3581 kHz crystal for W1AW bulletin reception and reported an "uncanny feeling" hearing the grand old station by campfire light in the midst of a dark forest!

Upon his return, we duplicated the typical field installation to take some measurements. The antenna was a quarter-wave "lazy inverted L" which rose 25 feet up from the rig, bent around a tree

limb, and then sloped gradually downward to a height of about seven feet. The ground system was an eight-inch tent stake (we said this was a worst-case scenario). SWR measured 4:1. No doubt confirming the high ground resistance and implying rather low radiation efficiency. Nevertheless, it worked.

We experimented with simple earth grounds and concluded that, for a Marconi antenna like this, three eighth-wave radials (33 feet long) far surpass the tent stake. SWR fell to 1.4:1 and relative field strength increased noticeably. On 40 or 30 meters (and 80 if you can), a simple half-wave dipole strung "inverted V" fashion would be hard to beat.

The 12-volt lantern battery, it turned out, was actually delivering only 11.2 VDC (key down) to the Spider, resulting in just 800 mW of RF output. A better choice would be nine or 10 carbon-zinc cells or 12 NiCds, "AA" size or bigger in either case. This way, the greatest portion of the battery discharge curve will be above 12 volts rather than below.

The "earbuds" used for listening had too much high-frequency response, resulting in unwanted background hiss even with the volume turned down. A pair of inexpensive mono earplugs Y'd together might do a better job in this application. All in all, the field trial was a success. We kept in touch, and afterward learned how to pick up an easy S-unit by optimizing the battery and earth ground.

maximum power output. The sidetone pitch should be distinctly lower if the smart-tone is working. Connect an antenna and adjust T2 for best receive when you hear a signal. That's it.

I experienced no difficulty with AM detec-

tion on 80 and 40, even though this receiver type is known to be prone. On 30 meters in the evening, a couple of North American broadcasters in the 31 meter band became intermittently audible, but code signals in the ham

band remained readable. Most other times 30 meters is clear. If you have a problem with AM detection, reduce the value of C15 to

Continued on page 30

Twin Crystal Ladder Filters

Upper or lower sideband filters using inexpensive crystals.

by John Pivnichny N2DCH

Crystal ladder filters are a good way to provide the selectivity required in single sideband transceiver equipment. Pochet¹, Hardcastle², and Hayward³ have described the basic approaches for these filters. Their unique characteristic is that all crystals used in a filter are of the same (identical) frequency. This allows you to make use of the low-cost "microprocessor" and "colorburst" crystals now available in a variety of specific frequencies. With these filters, it's no longer necessary to specially order and pay lots of money for specifically cut crystal frequencies.

In this article I describe two filters designed for lower sideband and upper sideband service using a common carrier frequency. Both filters are constructed from 9830.4 kHz microprocessor crystals available from DigiKey (Digi-Key Corporation, Catalog #925, page 110, part number X087, 9.8304 MHz crystal, 20 pF load capacitance).

A transmitter carrier frequency, or BFO in a receiver application, can be supplied by a single oscillator operating at approximately 9829.5 kHz and using another 9830.4 kHz crystal. A suggested circuit for this oscillator is given.

The filters are shaped to provide either upper or lower sideband operation with excellent suppression of the unwanted sideband. I suggest that you incorporate both filters in transceiver designs. In some applications, such as simultaneous transmission/reception of slow-scan video on one sideband and voice on the other, both filters could be in operation at one time. This simultaneous use of both sidebands is also referred to as "independent sideband," ISB⁴.

Figure 1. Calculated filter passbands.

Filter Circuits

Figure 1 shows calculated filter passbands; Figure 2 shows corresponding schematics for the two filter circuit diagrams. Note that the same terminating resistance is used for either filter. This is only possible through the unconventional use of an inductor at both ends of the lower sideband filter. The capacitor values for both filters were carefully selected to provide passbands which are mirror images reflected about the carrier frequency. The passbands are 35 dB down at the carrier and provide suppression of the unwanted sideband well in excess of 80 dB. Ultimate rejection of the other skirt is over 60 dB. These are very good figures for relatively simple home-built filters. They are easily duplicated with ordinary construction practices, as described below.

Crystal Measurements

The crystals are specified by Digi-Key as ± 50 parts per million at 25 degrees Celsius, with another ± 100 ppm from zero to 70 degrees C. Aging is another 10 ppm per year. This works out to be ± 492 hertz initial tolerance. I found the series resonant frequencies to be much better matched.

Using the 50-ohm test circuit shown in Figure 3, I measured a batch of 20 crystals and got the results shown in Table 1. The average series resonant frequency of the first eight measurements was 9,825,945 Hz with just over 100 Hz, plus or minus deviation. The average series resistance was 33 ohms ± 4 ohms. Motional capacitance is 0.02438 pF and motional inductance 10.76 mH. These were measured using Hayward's tech-

nique and formulas. The holder capacitance appears to be about 7 pF.

Measurements on crystals 9 to 20 also averaged 9,825,945 Hz (wow) with slightly over 250 Hz plus or minus worst case deviation. With such excellent matching, it is safe to recommend selecting crystals at random and just soldering them in to build the filters. It's not necessary to take crystal measurements first.

Of course, if you were thinking of building a CW bandwidth filter, then I would match the crystals to under 100 Hz, but with these SSB bandwidths, that just doesn't seem necessary. Duplicating these filters is much easier if you don't have to measure each crystal.

Note that the calculated passbands shown in Figure 1 were based on the measured capacitance and inductance values for the crystals given above. If you want to reproduce these calculations and have them come out exactly on frequency, then use a more accurate value of the motional inductance of 10.76113 mH.

Inductors

As originally designed, the lower sideband filter had a series capacitor of 118 pF at each end. The termination resistance was 201 ohms. I wanted to "step" this up to 2,831 ohms to match the impedance of the upper sideband filter. A step up is only possible if you add a series inductor and shunt end capacitor. In essence, the inductor cancels out some of the high reactance of the shunt end capacitor and makes it look like a higher value (lower reactance) series capacitor. You could also step up the impedance with a transformer using a ferrite toroid core.

The inductor value is not particularly critical because it is not resonant with anything in the neighborhood of 9.830 MHz. It is merely used for impedance transformation and normal tolerances are OK. Fifty-five turns of #30 gage copper wire on a T37-6 (yellow) toroid core gives the right value of

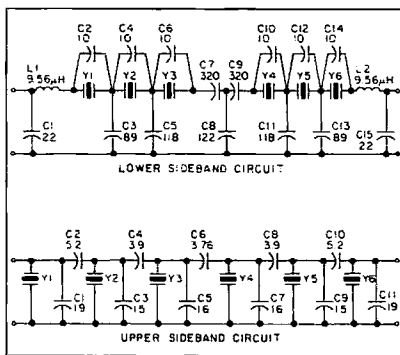

Figure 2. Filter schematics. All capacitors in pF.

Figure 3. 50-ohm test circuit.

Figure 4 (a). PC board foil pattern for the lower sideband filter. (b). Parts placement diagram.

Figure 6. Circuit for estimating insertion loss of the lower sideband filter.

inductance, with a Q of about 160. You can check the value quickly by temporarily soldering a 100 pF capacitor across the ends of the wound toroid. Leave enough lead length to form a one-inch-diameter loop. Then check the resonant frequency with a dip meter placed near the loop. It should read about 5.15 to 5.17 MHz. If it's way off, add or remove a turn or two.

Capacitors

Like the inductors, the capacitor values are also not particularly critical. I used small 50-volt ceramic capacitors from NTE (tolerance unknown). If you want to be a purist about it, go with silver miccas, but I don't think that's necessary in a home-built filter.

Construction

I use one-ounce, single-sided epoxy glass circuit board cut into a 3/4-inch strip with a coping saw. With the foil side up, I mark component hole locations by eye with a sharp-pointed metal scribe. Then I drill the marked points using a #60 drill bit (0.040-inch diameter) in a hand drill. Points which connect to the ground plane are left as is, and all other holes are countersunk with a 0.12-inch diameter bit. About five turns of the hand crank of the drill is enough at each hole. This leaves a nice insulated through-hole position. The remaining epoxy glass holds the component lead centered in the countersunk hole.

A 2-1/2-inch length of circuit board was enough for my upper sideband filter. This may vary somewhat depending on the size of your capacitors, but mine required three inches for the lower sideband filter in order to fit in the inductors. I fastened down the inductors with a 4-40 nylon machine screw and nylon nut after first placing one layer of black tape on the foil under the inductor.

Components are then inserted and sol-

Figure 8. Calculated passbands with series resistance included.

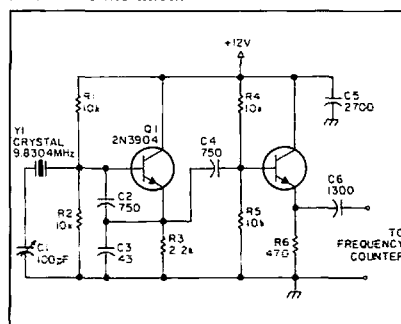

Figure 9. Oscillator circuit for use as a BFO or transmitter carrier.

dered together on the back side. Ground connections are made on the front side as needed. This drilling technique makes an excellent filter. If you're going to build many copies of the filters, then an etched circuit board might be in order, but for just one or two, the drilling approach is faster and pro-

Figure 5. (a). PC board foil pattern for the upper sideband filter. (b). Parts placement diagram.

Figure 10. (a). PC board foil pattern for the oscillator circuit. (b). Parts placement. Note that the 50-ohm test circuit shown in Figure 3 is incorporated on this board.

vides a solid ground plane for shielding.

[Ed. Note: Etched and drilled PC boards are available for the two filters as well as the oscillator test circuit from FAR Circuits. The foil patterns and parts placement for these boards are shown in Figures 4 and 5.]

Final Check

How do the actual filters compare to the calculated responses? Well, the high series resistance (33-ohm) of these microprocessor crystals creates an insertion loss and distorts the pattern somewhat. One way to estimate this loss for the lower sideband filter is to temporarily ignore the reactive elements, the capacitors and inductors, and just look at the resistances (see Figure 6). Use the original termination, before stepup, of 201 ohms. Note—the impedance stepup does not

change the insertion loss.

The crystal series resistors create a resistive voltage divider circuit between the filter input and the final terminator, points a and b in Figure 6. The loss is:

$$\text{Loss} = \frac{198}{201 + 198} = 0.496 = -0.9 \text{ dB}$$

I haven't found any easy way to estimate the insertion loss of the upper sideband filter. It turns out to be about the same, however, preserving the symmetry of the two filters.

My actual measurements of the filter passbands are shown in Figure 7. These are only approximate because of the limitations of my simple home-brew instrumentation. Note the more rounded passbands but still very steep skirts. Reasonable symmetry and spacing between the two filters demonstrates their usefulness for upper and lower sideband service. If the series resistance is included in the calculated frequency sweeps (it was neglected in Figure 1) then the same rounded off tops and insertion loss show up—see Figure 8. In fact, there is good agreement between the calculated and measured results.

An Oscillator

The carrier oscillator in a transmitter or BFO in a receiver should be placed at the frequency where the two passbands cross. This point is between the series resonant frequency of the crystal and the specified 20 pF load parallel resonant frequency of 9,830,400 Hz. So an oscillator circuit can be built using another crystal of the same frequency as those used in the filter. The load capacitance will have to be slightly higher than 20 pF in order to "pull" the oscillator frequency down a little.

Using the oscillator circuit shown in Figure 9, which I had already built up for an earlier project, I found the frequency could be pulled from 9,833,393 Hz down to 9,828,485 Hz by adjusting the 100 pF trimmer capacitor from a minimum of about 10 pF to its maximum of 100 pF. This is more than enough range to properly place the carrier frequency. The measured passbands cross at 9,828,700 Hz. The oscil-

lator PC board foil pattern and parts placement are shown in Figure 10.

Conclusions

Ladder crystal filters are ideal circuits to use in constructing homemade hardware because specially-cut frequencies are not needed. Low cost microprocessor crystals can be used to construct very satisfactory filters. This article shows that both upper and lower sideband filters can be made using a single crystal frequency, greatly enhancing their potential for use in multiband transceivers. They can also be used for independent sideband, ISB, service.

It appears that satisfactory filters can be built simply by purchasing low cost parts and "hooking them up." No special equipment or tuning or experience is required. So if you like to build your own ham radio gear, why not give these filters a try?

Price Class: Complete kit of parts including

3 PC boards and a crystal, \$155;

add-on PA kit without enclosure, \$75;

with enclosure, \$135;

432 MHz preamp kit, \$30.

Enclosures available.

The key to the growth of amateur radio in the future is to use the spectrum space above 148 MHz—valuable frequencies which are coveted by other potential commercial users. Yet, many amateurs have been discouraged by both the high cost of commercially-available multimode transceivers and the complexity of older "do-it-yourself" designs.

Down East Microwave breaks through both barriers with the DEM 432K, an easy-to-build linear transverter which offers excellent performance at a reasonable price and uses state-of-the-art broadband design technology to eliminate most of the bench work necessary to fire up the kit when completed.

How It Works

The DEM 432K consists of three boards: a local oscillator (L70), a receive mixer and converter (R70), and a transmit mixer and converter (T70). All stages are truly linear, meaning any input mode can be reproduced faithfully. The combination of boards will upconvert your low-level transmitted signals from 28-30 MHz to 432-434 MHz, and will downconvert received signals in the opposite direction.

The LO multiplies a crystal frequency of 101.00 MHz four times to 404 MHz, then amplifies and buffers the output for stability. An on-board splitter gives you two outputs of +8 to +10 dBm, which feed both the transmit and receive converters. The only tuning adjustment which is made is to trim the crystal frequency right to 404.000 MHz—all other circuits are broadbanded.

The receive converter has NO tunable circuits, just a pair of Microwave Monolithic Integrated Circuits (MMICs) driving a Mini-Circuits mixer assembly. Overall conversion gain is about 10 to 12 dB, and an onboard GaAsFET preamplifier improves system gain to about 20 dB with a noise figure of about 0.5-0.6 dB.

The same is true for the transmit converter, which uses three MMICs to develop output at 70 cm. The nominal output is about +16 dBm linear, or close to 50 milliwatts of RF. Adding an S-AU4 power module will result in 15 to 20 watts of output power, depending on your power supply voltage.

Construction

I ordered the whole nine yards from Bill Olsen, getting all three boards plus the S-AU4 PA kit. After wandering around several electronics parts distributors, I located a pair of enclosures for the PA, as well as the entire transverter assembly (Photo C). This was a neat trick as I hadn't even started construction yet! Longtime Microwave Modules users will recognize the approach I took right away, se-

Photo A. The DEM 432K transverter kit (case not included). The receiver (R70) and transmitter (T70) boards are stacked underneath the LO (L70) board. The PA module (432PAK) is shown on the right.

Photo B. Close-up view showing connections between the transverter and the PA modules. The small board at the bottom is the optional preamp (designed by Steve Kostro N2CEI).

Photo C. All modules fit nicely in PAC-TEC die-cast enclosures (not included in kit).

lecting PAC-TEC UE-692-900 and UE-351-900 die-cast boxes.

Each of the boards and its associated parts comes in a zip-lock bag, and a nine-page manual with pictorial diagrams and schematics for assembly is included. The most complicated board to assemble is (as you might have guessed) the local oscillator. One note of caution: All of the boards make extensive

use of microwave chip capacitors, which are very small and easily lost! My "trick" is to double up a piece of masking tape on my working surface, then stick the components to it and pull them off one at a time as needed. The chip capacitors are secured with transparent tape to a small card which identifies them by value. Your best bet is to solder all of the capacitors from each group before moving on to the next. In addition, a few chip resistors (very tiny!) are also attached to the card. Make sure you use a low-wattage soldering iron and a good pair of precision needle-nose pliers to install all chip components.

Aside from these few precautions, kit building should proceed quickly. All of the MMICs are securely packaged and labeled, and the instructions provide a visual key as to package orientation and lead length. BFX89 transistors are used as the oscillator and first buffer, and one lead will need to be clipped from each. This is shown in the assembly manual. You'll also need to wind a few coils from #24 insulated wire on a 0.1" (#33) diameter drill bit. While tedious, this shouldn't take long. Make sure you scrape the insulation from the leads before attempting to solder them!

You can build the boards in any order you like. The local oscillator board has extra pads for a second complete local oscillator to allow switching band coverage for satellite operation. (The extra components can be ordered from Down East Microwave.) Use miniature Teflon coax for all of your interconnects between boards to keep losses down. Use care when installing the TUF-1 mixer assemblies! Don't bend the leads excessively, and watch the case orientation, as spelled out in the instructions.

Powering Up

About the only thing you'll have to do is get the local oscillator up and running. A VOM set to 250 or 500 mA scale is all that's required for the bare-bones setup, but a frequency counter would also help. After checking your component installation, apply 13.8 volts DC and rotate C1 through its range. You should see a definite peak on the VOM as the oscillator kicks in, and this should be very close to 101.00 MHz. LO current should be about 150-200 mA.

Next, check for 404 MHz output at both of the connections to the T70 and R70 mixers. If you can measure RF millivolts, anything from +7 to +10 dBm is acceptable. Trim C1 to get as close to frequency as possible—if not, add another turn to L1 and try again. Additional

Handi-Beacon

Turn your tape recorder into a beacon controller.

by Klaus Spies WB9YBM

The need for beacons extends beyond propagation tests. They are also very useful for range tests and equipment checks (two aspects seldom considered). Quite frequently, I have made an adjustment to my radio and not had anyone at home to help with a range test. To help solve this dilemma, I came up with a way to turn a transmitter into a useful beacon using a tape recorder and a simple interface.

My initial test setup consisted of a rubber band wrapped around a radio's microphone (to hold down the PTT) and placed near the speaker of a tape recorder. Unfortunately, this proved unreliable—if one of my cats knocked the microphone off of the tape deck or someone accidentally turned off the tape deck, I would lose both the station identification and test audio (to check readability at the noisy fringe area).

Beacon Tape Recorder Interface

This led to the development of the circuit shown in Figure 1. One operational amplifier acts as variable gain stage, to feed audio to the transceiver's microphone audio (U1A/U1C) from the tape deck's output. This direct connection eliminates any background noise feeding into the transceiver. The second operational amplifier (U1B/U1C) drives the audio into clip. The slopes of this signal are steep enough to be seen as digital by the 4538 timer (U2A/U2B) (see Table 1), which is wired as a retriggerable leading edge oscillator. When the audio starts, the 4538 is triggered, activating the transceiver's PTT. If for some reason the audio vanishes, the radio will toggle back into receive as determined by the time constant of the 4538 (calculated by $T=RC$), which I set for two seconds (plenty of time to ensure that the transceiver does not toggle between words).

For convenience, I typically use an endless-loop tape. For long tests, I am very careful about the trans-

mit time of my transceiver. For example, if I know that the power levels being used will cause a rapid heat-up of either the transceiver and/or the amplifier, I'll use a 60-second tape, with only about 30 seconds worth of talking, for a 50% duty cycle. If you find your system still gets unacceptably warm, try for 30% or 40% transmit time (for those who want to put up a high-powered beacon). A simple ID is usually sufficient; something like, "WB9YBM, Niles, Illinois-test" should both satisfy the FCC and provide a long enough transmission to let a mobile station drive in and out of several signal nulls. For propagation beacon applications, you may want to add information about your power level and antenna height. You can also offer a QSL in exchange for a reception report if you'd like an idea of how well your beacon is performing as well as help in studying propagation.

Since only half of the 4538 is utilized, I chose to make two independent beacons out of one circuit. There is still the need for only two ICs—the dual operational amplifier was upgraded to a quad package, keeping the project simple. If the same cassette tape is used for both beacons (each on a different band, using different antenna heights or types, or just different power levels), a stereo tape player can be used to feed both (either both tracks of the tape can initially be

recorded in monaural to provide identical information to both tapes—in which case, a generic identification will be preferred—or each track of the tape can contain separate information).

No special recorders are required; any cheap play-only deck will do. If you plan to put the beacon at a relatively inaccessible spot, the primary stipulation will be a good quality tape that will not degrade too quickly with high levels of use.

CW Beacon Applications

For a CW beacon, simply record CW on the endless loop tape and re-calculate the time constant of the 4538 as follows: If the recorded CW tone is 1 kHz, the 4538 will get triggered once every 0.001 seconds. Therefore, to avoid having the output of the 4538 give a steady output, its hang time must be longer than 0.001 seconds ($1/1,000$ Hz), but short enough to unkey at almost the same time as the CW tone on the tape. For other tone frequencies on the tape, just use the formula $1/f$.

If a CW tone and keying are desired (to feed CW tones to a VHF FM transceiver's audio input while at the same time keying the PTT line), you can use a 555 timer set to run at 1 kHz (the approximate center of the audio passband of most transceivers and a tone many people are most sensitive to) and

The next generation of store-and-forward voice controllers.

It is a great pleasure to see an equipment manufacturer make subtle improvements to a recognized good product. It tells me that they are not satisfied with "resting on their laurels." It also indicates that there are people who feel that radio amateurs are a progressive lot who like to experiment. Not only has this company improved their product, but they did it in a manner that I feel will encourage experimentation. The evolution of this product is not apparent from the look of its case or front panel but is quite obvious from a functional point of view.

About 18 months ago, I had a chance to review a product known as the SR3 Simplex Repeater from Brainstorm Engineering in La Crescenta, California (73 *Amateur Radio Today*, May 1991, page 46). Brainstorm implemented several substantial internal enhancements to the SR3, and renamed it the SR4, then Alinco and Brainstorm joined forces. If you place the SR3 and SR4 side by side there are virtually no noticeable differences. Functionally, however, the SR4 has evolved into an extremely flexible system of integrated transceiver control.

Some Additional History

The first thing that I would like to say is that the SR4 is much more than a simplex repeater. Depending on the model of the SR4 acquired, it can also be a very capable full-duplex repeater controller. The SR4 retains all the functions of the SR3, with the addition of many more. The biggest improvement, however, is the flexibility with which the SR4 may be configured to interface with virtually any transceiver.

My review (identified above) provides a good background on this product, but for those of you who don't have access to this article, I will synopsise it here. I will then review the many enhancements and new functions offered by the SR4.

The simplex repeater is effectively a voice store-and-forward device. Hardware requirements are minimal. Only one voice-standard voice-grade transceiver and antenna are required for its operation. When the connected transceiver receives a sig-

The SR4 multimode simplex repeater from Alinco.

nal, the simplex repeater digitizes its audio output and stores it in solid-state memory. When the transmitting station finishes, the simplex repeater keys the same transceiver and plays back the captured audio, effectively repeating it to any user tuned to the transceiver's frequency. There are no duplexers involved and no desense (because the receiver and transmitter are never active at the same time). Even the originating station gets to hear his or her own signal as the transmission doesn't get repeated until the originating station drops carrier. While it isn't as conducive to back-and-forth chitchat as a full-duplex repeater, it's simple to set up and quite portable. And, since the SR3 and SR4 don't use any mechanical tape transport as the voice storage media, they are also quite reliable. Older simplex repeater systems used analog tape drives which were slow (they had to rewind before the received message could be repeated) and prone to mechanical problems.

The Physical Device

The Alinco SR4 is packaged almost identically to the SR3 (the only difference is in the front and rear panel labeling).

Both units are contained in attractive, strong black metal cases 10.5" wide by 6" deep by 1.75" high. The power requirements are 11.6 to 15 VDC at about 160 mA.

The documentation is excellent. It should be realized that the SR4 is a complex radio interfacing device. Almost all analog signal inputs and outputs, whether they be control, data, or audio, may be tailored via internal adjustments. The documentation goes into considerable detail on how to optimize each parameter. This device is an experimenter's dream! Providing that the person who is initially setting this up has a reasonable level of technical competence, I cannot foresee any transceiver or device that will not work well with the SR4.

SR4 Functionality

The SR4 comes in two models. The first, the SR4, will control one radio and functions as a simplex repeater (with voice ID and mailbox functions). The second, the SR4-D, will control two radios. As well as being a simplex repeater, it will also function as a full-duplex repeater controller. This review is applicable to the SR4-D.

CIRCLE 55 ON READER SERVICE CARD

The SR4-D is capable of several functions. The primary function of simplex repeat has several improvements over the SR3. Perhaps the most dramatic is the Receive VOX method of COR detection. It is not necessary to pick off a hardware COR from the transceiver or have the transmitting station use CTCSS. The SR4-D will generate its own carrier detection from the audio output of the connected radio. The only requirement is that the audio must be squelched. Any signal-breaking squelch will generate an active COR and either start the unit recording in the simplex repeat mode or key the second transceiver in full-duplex repeat (if that mode is selected).

The Receive VOX COR detection has three internal adjustments: attack time, hang time, and overall sensitivity. Each of these is independently controlled via internal pots. Using the SR4-D with two old Heathkit HW-2036 transceivers yielded very reliable repeating in both the simplex and full-duplex modes once the RX VOX adjustments were optimized. Unless the transmit and receive frequencies are widely separated, a duplexer is still necessary in full-duplex repeat. Another versatile capability of the SR4-D is its ability to simplex repeat on one radio while full-duplex

position, the audio was noticeably better.

Additional Features

The SR4 has a plethora of additional features that will delight the experimenter and tinkerer! COR detection for simplex and full-duplex repeat may be achieved by several methods: by the receive VOX method described above, by listening for a CTCSS tone (with the optional TS32P decoder available directly from Brainstorm Engineering, 2948-1/2 Honolulu Ave., La Crescenta CA 91214; Tel: (818) 249-4383), or by sensing a hard voltage level change from the connected transceiver (with the optional HW2 Hardware Carrier Detector from Brainstorm).

Hardware COR from the radio may be either a positive or negative swing and may be as small a change as 300 mV. All audio levels in and out are fully adjustable via internal pots. The SR4 is also configurable to a wide range of microphone input circuit impedances via internal jumpers.

The SR4 has a full-featured DTMF decoder. Virtually any function of the unit may be controlled remotely. Commands sent to the SR4 will be verified by an acknowledgment tone. There will be a short tone if the command is accepted and a longer one if not. The SR4 may be completely

The SR4 has a plethora of additional features that will delight the experimenter and tinkerer!

repeating via the other. Both simplex and duplex repeat functions may be controlled via DTMF tones.

Voice ID and Voice Mail

The SR4 has a voice IDer that users can program with their own voice. This is done remotely via a DTMF-equipped transceiver. The activity timer, which controls the periodicity of the ID function, may be remotely DTMF programmed from one to 98 minutes. You are not limited to voice; you may use an electronic keyer and record a CW ID if desired. Voice ID messages may be recorded, played back, and erased at any time via DTMF control.

The voice mail function enables a user to store a voice (or any other audio) message for retrieval at a later time. The SR4 will only store one message at a time. When a message is stored, the SR4 generates a unique squelch tail to alert users. The message may be played as often as desired. When the voice message is erased, the squelch tail is removed.

The SR4 has a total of two minutes and 48 seconds of total audio storage capability. This is split between the simplex repeat, voice IDer, and voice mail functions. I tried both voice IDer and message functions. There are two audio sampling rates. In the low rate, the audio was a bit raspy but still quite acceptable for its intended use. In the high sampling rate

Inhibited from operating or enabled from an inhibited state via DTMF control. The power saver function may be enabled/disabled.

This is a useful feature which prevents the front panel LEDs from lighting to save power during battery operation. All repeat functions of either connected transceiver may be controlled. Either radio's receiver or transmitter interface to the SR4 may be turned on or off, and either radio may also be put in or out of the simplex or full-duplex repeat mode. The roger beep/courtesy tone may be enabled/disabled and all aspects of the voice mail or voice ID may be controlled. This includes recording, playing and clearing messages and voice IDs. The SR4 may also be inhibited from passing DTMF tones on the air via its repeat function. Finally, the SR4 has an auxiliary output which may be used to control a relay or similar device.

Soon to be released features are a multi-user voice mail system, 11 minutes of digital storage time and a simplex and duplex autopatch.

Writing a review for a device like the SR4 is difficult at best. I don't believe that any two individuals will use it in the same way. Reading the SR4's manual and experimenting with the unit itself will start the creative juices flowing. It is an excellent addition to your club's repeater or your home station.

Radio Direction Finding

Joe Moell, P.E., K0OV
PO Box 2508
Fullerton CA 92633

Computers Point the Way

Living in Southern California has its good and bad points, but one big advantage for hams is being able to go on hidden transmitter hunts all year long. Radio direction finding (RDF) enthusiasts in northern states and Canada have a few months of cold weather and icy roads ahead, so many clubs there will not be holding these contests (called foxhunts and T-hunts) until spring.

That doesn't mean you should forget about this part of ham radio, however. Now is the time to plan and build a better RDF setup, in anticipation of the thrill of victory when hunts resume. What will your new secret weapon be?

The "radar scope" display, described in "Homing In" for October and November 1992, generated lots of response. Readers like the two-dimensional view of the hidden signal, but some have had trouble finding suitable storage oscilloscopes. Furthermore, these scopes are bulky and difficult to power up in a vehicle.

Why not use a computer screen for the readout device? A laptop portable is small and lightweight. It works from its own batteries, or perhaps 12 volts from the vehicle. Best of all, the computer can "crunch" the data to aid in finding the most accurate bearing and navigating to the hidden T.

Heads Up!

Jerry Boyd WB8WFK of Albu-

querque, New Mexico, is a pioneer in computer-assisted mobile RDF. When I first met Jerry in October 1991, he had installed a continuous-turning potentiometer at the base of the mast for his four-element 2 meter T-hunting yagi (Photo A). It drove a dash-mounted meter that gave him a "heads-up" indication of antenna pointing direction.

This remote azimuth indicator is an easy weekend project. Figure 1 shows the schematic for it. Jerry used a surplus Bourne's precision linear taper pot (R1). U1 can be any op amp IC that works as a voltage follower at DC. Regulator U3 is used as an active voltage reference. R3 adjusts its output to +3.4 volts (corresponding to 340 degrees), measured at TP1.

Jerry's azimuth pot has 340 degrees of winding and a 20-degree dead zone. He says, "Between 340 and 359 degrees the arm of my pot goes open circuit. R6 prevents the output of U2 from floating when the pot is in this dead zone." Align the indicator so that when the antenna points forward, the pot is at the 180-degree setting and output voltage at TP2 is 1.8 volts. This puts the dead zone behind you where it has the least effect when T-hunting. Calibrate the meter by setting R8 for a 180-degree reading on M1 at this R1 setting. If you are not using a 100 microampere meter movement, change the values of R7 and R8 accordingly. Movements from 50 microamperes to 1 milliampere can be used with appropriate changes in these resistors.

Photo A. This is how WB8WFK attaches the bottom of his mobile antenna mast to the azimuth-sensing potentiometer. The assembly mounts to the inside of the driver-side door.

Photo B. Interior view of the interface box containing the MUX, A/D converter and Micromint computer board. BNC jacks on the rear are analog data inputs. (Photo by WB8WFK.)

Going Digital

Today, WB8WFK's huntmobile boasts an integrated digital bearing-taking, storage, and display system. The nerve center of the system is an interface box (Photo B) that includes

a home-brew eight-channel analog multiplexer (MUX), analog-to-digital (A/D) converter, and a Micromint Z8 single-board computer (Figure 2). Analog signals representing antenna azimuth, S-meter, and RF attenu-

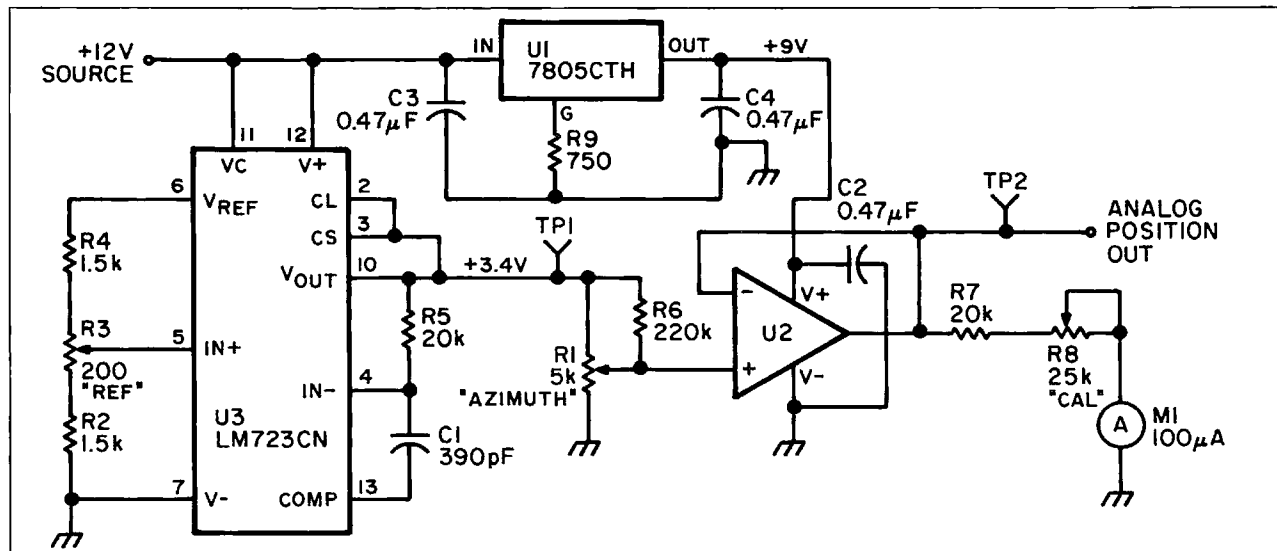

Figure 1. Schematic of the antenna position display unit. R1 is the continuous-turning potentiometer. M1 indicates direction. The analog output goes to the MUX and A/D converter.

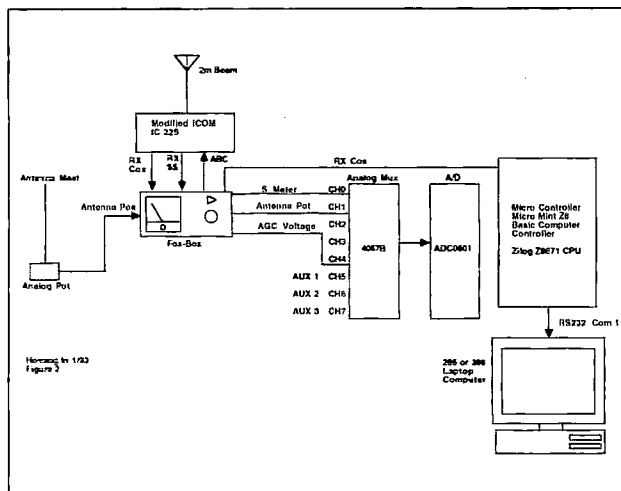

Figure 2. Block diagram of WB8WFK's system. Analog outputs of the fox-box are digitized and then processed by the controller and laptop computer. Extra MUX channels are available for inputs from a flux-gate compass and digital shaft encoder.

ation go from the box to the MUX. The Z8 takes the digitized data and transmits it to a PC-compatible portable computer via the RS-232 port. The computer is programmed to use the serial azimuth and signal strength data to compute and display polar plots (Figure 3).

"Ed James KA8JMW loaned me a 386 laptop (Photo C) for the display unit," Jerry says. "But even with this fast computer, the plotting is not done in real time. I push a button to trigger a data acquisition. The program takes 256 samples of antenna angle and signal strength and stores them in an array. It samples at about 10 times a second. Then it quits sampling, draws the plot, and computes the best bearing. "Next, I have the option of scaling the plot. Say the S-meter reading was low, so the trace was small. I can enter a scale factor to expand the plot to full size. I'm thinking of making the software compute the scale factor automatically."

Like most VHF T-hunters who use beams, WB8WFK turns his mobile antenna mast manually. The 25-

Photo C. WB8WFK's car is ready for the hunt. The analog fox-box and digital interface unit are on the dash. The computer (protected by pillows) has replaced a human in the passenger's seat. (Photo by WB8WFK.)

direction of interest and improves the accuracy of his bearings.

Jerry adds, "One of the software features is that it walks through the data array to find the signal peak and the corresponding angle to the peak. On the screen I see the polar plot, plus a status panel with best bearing details on the side.

"I used it on a real hunt Sunday. It

gram for data display is in Microsoft Quick Basic 4.5. On my old XT it takes 45 seconds to do the plot. On the 386 laptop, it's five seconds." Jerry says that other computers besides IBM compatibles could be adapted to this system. "Ed has a Radio Shack Model 100 and we're thinking of seeing if we can make a version of the software that runs on it, using an X-Y plot of signal strength versus azimuth instead of a polar display. Model 100s don't have the screen resolution to do a polar plot, but they're real cheap at hamfests."

Next month's "Homing In" will have more details on the software features, plus schematics and parts information for the interface box. Jerry's strong signal attenuation scheme will also be described.

I'll bet other readers are working on digital processing for their RDF equipment. If so, I'd like to hear about it. Write and tell me what you are doing. Better yet, get out the camera, take some pictures, and send them to me. Let's share ideas.

“Fluctuating signals and noise show up as a ‘spikey’ display compared to steady signals, which produce well-rounded lobes.”

show up as a “spikey” display compared to steady signals, which produce well-rounded lobes (Figure 5).

On some hunts there is only one apparent signal direction, but the amplitude fluctuates due to nearby moving objects, airplane flutter, or power changes by the transmitter hider. When that happens, Jerry sweeps back and forth across the signal when taking data, instead of turning the antenna in a full circle. This builds up multiple traces in the

shows direct signal and reflections real nicely. What really surprised the other hunters was that after the hunt I could play back the bearings. I have a feature in the software that saves data to a disk file for later review."

It's All in the Software

"The Z8 control program is written in Tiny Basic and is downloaded to the Z8 by the DIGDF program on the PC," Jerry says. "The pro-

Figure 3. Rotating a high gain beam produces this pattern on the computer screen when there are no fluctuations, reflections, or multipath. (Of course, this never seems to happen on an actual hunt!)

Figure 4. A complete screen dump from WB8WFK's digital RDF system in the field. It's easy to tell the direct signal from the fluctuating reflection. The peak locator shows that maximum signal is coming from 84 degrees with respect to the vehicle heading. The S-meter reading was multiplied by 1.8 for a full-size plot. Attenuation, compass, and LORAN indications have not been fully implemented into this software version.

Figure 5. This plot was taken in a supermarket parking lot on an Albuquerque T-hunt. The spikes at zero degrees represent noise from power lines ahead of the vehicle. The hidden T is to the left and there is reflected signal from the right.

Do You Have the Write Stuff?

Every time a new issue or controversy comes up that affects our lives in some way, we as American citizens have the right and the obligation to let our elected officials know what our points of view are on the matter. Whenever an important new rule is being proposed that affects the amateur radio community, most of us have strong feelings pro or con on the issue before us. Usually, some member of an active radio club will organize an effort to make it real easy for the membership to express their opinions by signing a petition or by getting a massive letter-writing campaign going.

As an amateur radio teacher in an intermediate school, I like to seize upon these opportunities to teach a civics lesson and a language arts lesson as well. After we discuss the issue and the children do the required research to present their arguments to the rest of the class, we talk about what our best options are to get our opinions across to the people with the power to enact legislation and to make changes.

In 1990, the United States Postal Service handled about 60 billion first-class letters and packages. That means that the average American household sent about 620 letters that year. Were any of them sent to a senator, representative, FCC Commissioner, or other government official? In most households, the response to that question would be "no."

It's important for children to know that writing to Congress or other branches of the government is still one of the most effective things that a citizen, as an indi-

vidual, can do. According to the Office of Legislative Information and Bill Status, thousands of bills get introduced during each session of Congress. By speaking out on any of these bills, you automatically increase your "political clout." Many members of Congress consider opinions expressed in a letter to represent at least 100 votes.

Guidelines for Writing to Congress

The children always enjoy writing their opinions in a letter when the point about its importance is made clear to them. I use the following guidelines with my classes to ensure the most effective response.

When writing to Congress, personal letters are preferable to preprinted cards. A veteran lobbyist says that, "Handwritten letters show that a person has taken the time to think about an issue and has a viewpoint on it. The more people write out of their own convictions, the more likely they are to get a response."

Write about one topic at a time. Make your point and don't confuse the issue with other extraneous information.

Letters that are short and to the point are more likely to get read. Legislators often use letters simply to get a count of the number of people who support or oppose different bills.

In your first sentence, state that you oppose or support a specific bill or issue, so it will be easy to tell which side you're on.

Postcards are easier to send and easier to read.

If you're referring to a bill, make sure you have the right number and title. This is very important due to the large number of bills that get introduced every year. You can get this information by calling your local Congressional office. Put some kids to work on this as-

Photo A. Eighth graders Matt KB2QJ and Bianca are examples of children who love to get involved with local, national and international issues through ham radio.

pect of the preparation and research. It's good experience for them to start to learn their way around their own government.

State your case. Show that you understand the issue and explain how it affects you, your family, and your community.

If it's appropriate, send a "thank you" letter once the issue has been decided. According to one expert, for every 100 to 250 letters that legislators receive in a week, only about two are "thank you" letters. If you send a thank you letter, you may stand out enough that they'll remember you the next time you write.

One of our goals as educators, no matter what subject area we teach, should be to make sure that our students know the importance of being well informed, and then know what acceptable channels to go through are

available to let their voices be heard. Teachers using amateur radio in their classes have many unique opportunities to teach about the responsibilities that go along with being a good citizen of their community, their state, their country, and of the planet. The nice thing about it is that there's always something going on somewhere either locally, nationally, or internationally that can lead into a great classroom lesson.

Besides liking the idea of making their own statements, my classes eagerly await the reply comments. Everyone in the class gets excited when official-looking correspondence comes to the school, addressed to them.

If you've had some interesting experiences getting your classes involved with the system of how government works, please write to me so we can share the ideas.

GIVE YOUR HR-2510 HR-2600 the same features as the "BIG RIGS"

- 30 Memory Channels
- Automatic Repeater Offset
- Programmable Transmit Timeout
- Programmable Seek/Scan (5 Khz, etc)
- Programmable Mike/Channel Buttons
- Programmable Transmit Freq. Limits
- Extended Frequency Range (10 to 12 meters)
- Priority Channel
- Split Frequency
- Many More Features

Using The Passive Double-Balanced Mixer (DBM)

The double-balanced mixer (DBM) is a terribly useful RF electronic component. It can be used in receivers, transmitters, test equipment and many other applications. It provides good mixing action with little of the hassle and headaches that accompany active mixers (transistors, ICs, etc.). The DBM is truly a versatile little beastie.

Figure 1 shows the generic circuit for the DBM. The mixing action is caused by a diode ring (D1 through D4), which is not, by the way, the same thing as a full-wave bridge rectifier (look at the diode directions). Coupling into and out of the circuit is provided by the RF input (RF), local oscillator (LO) and intermediate frequency (IF) ports; these are coupled via broadband RF transformers.

The Mini-Circuits SRA Series

While it is relatively easy to make working DBMs using signal diodes and toroid transformers, it's just as easy to buy high quality parts from a source such as Mini-Circuits (P.O. Box 350166, Brooklyn NY 11235-0003; 718-934-4500). Their SRA and SBL series DBMs are used extensively in ham construction projects shown in various publications over the years. The SRA-1 works from 500 kHz to 500 MHz (both LO and RF), and produces an IF output of DC to 500 MHz, depending on the LO and RF frequencies; the related SRA-1-1 works down to 100 kHz. Another model, SRA-2, works over the range 1 to 1,000 MHz (RF/LO), and produces IF outputs in the range 500 kHz to 500 MHz. The SBL series is similar to the SRA, but they are somewhat smaller. Prices in small quantities are in the \$15 range (consult the Mini-Circuits catalog for current pricing of any particular model).

The SRA-x devices come in a small, shielded metal housing that is 0.4 inches tall, 0.4 inches wide, and 0.8 inches long. It has eight pins on the bottom side, spaced 0.100 inches apart (see Figure 2). The pin spacing is the same as for most dual-inline package (DIP) integrated circuits, so the SRA series DBMs can be used on the standard perforated board that many hams like to use for construction. The number 1 pin indicated by the insulation around the pin is blue in color. All other pins are either connected to the case or embedded in gray or white insulation material. The pin numbers are arranged in zigzag order so that all of the odd numbered pins (1,3,5,7) are on the same side, and

the even numbered pins (2,4,6,8) are on the opposite side.

For the SRA-1 and SRA-1-1, which are probably the most popular with ham operators, the following pinouts are found:

Local oscillator: 8
RF input: 1
IF output: 3,4
(must be tied together)
Case ground: 2
Other ground: 5,6,7

The SRA-2 is similar, except that the RF input is placed on pins 3 and 4 (tied together), while the IF output is taken from pin no. 1. There are other models than SRA-1, SRA-1-1 and SRA-2, and these may have different pinouts than shown here. Consult the Mini-Circuits data for particulars.

The electrical performance of the SRA series DBMs is impressive for such low-cost parts. Isolation of the LO-RF circuits is on the order of 25 dB at the high end of the frequency range, and 50 dB at the low end. Similar numbers are found for LO-IF isolation as well. They use a +7 dBm LO signal, and can handle up to +1 dBm RF signals; these translate to 15 mW (15.8 mV) and 1.26 mW (7.9 mV) dissipated in a 50-ohm resistive load, respectively. The standard RF system impedance (50 ohms) is used for the SRA-series inputs and outputs.

Conversion loss in the passive mixers ranges from 6.5 to 8.5 dB, and this is easily made up with a simple amplifier if it can't be tolerated. In fact, the Mini-Circuits MAR-xx series of MMIC amplifier devices can easily be used for this purpose. One of Mini-Circuits other products is a series of active double-balanced mixers, in a similar case as the SRA series. These devices place an amplifier and DBM inside the same housing. The UNCL-X1 is similar to the SRA-1, except that it provides an output buffer for the IF port. The conversion gain (not loss) is 0.5 to 1 dB over the 1 to 500 MHz frequency range. The UNCL-R1 places the amplifier ahead of the RF port of the mixer, so it can accommodate RF signals up to -10 dBm, but also those that are considerably -10 dB weaker than will operate with the SRA-1. Conversion gain for the UNCL-R1 is 2 to 5 dB. The UNCL-L1 places the amplifier ahead of the DBM LO port, so it can accommodate weak LO sources. Conversion loss (not gain) is on the same order as for the SRA-1. The power requirements for these devices are similar: 12 VDC at 35 mA or so.

Figure 3 shows a typical "generic" circuit for the SRA-1 and SRA-1-1 mixers. The RF, LO and IF ports are protected by DC-blocking capacitors. These capacitors are necessary because the DBM must often operate in circuits that have a non-zero DC level,

or with signals that have a considerable DC component. The DC can burn out the windings of the input and output transformers. Of course, if there is no possibility of that happening in your particular application, then don't worry too much about the capacitors. In general, 0.01 μ F disk ceramic capacitors will work in the HF region, while 0.001 μ F (or even 100 pF) will work in the VHF region.

Notice that the two IF pins (3 and 4) are tied together. This connection is necessary, or else the device won't work properly. Also connected together are the ground pins (2, 5, 6 and 7). All of these pins must be grounded for proper operation, even though pin no. 2 is only the case ground (it serves to shield the innards of the device).

Any number of output circuits can be accommodated, so long as they

Figure 1. Circuit for a double-balanced mixer.

Figure 2. Pinouts for the Mini-Circuits SRA-series.

Figure 3. Generic circuit for the SRA-1 and SRA-1-1. The SRA-2 uses slightly different pinouts.

Figure 4. Low-pass filter output circuit.

are a reasonable match to the 50-ohm impedance of the SRA-1 and SRA-1-1 devices. A double-balanced mixer has some interesting properties. For example, it is more free of harmonics than other mixers, and it suppresses the LO and RF signals in the output. Thus, the spectrum of the output signal consists of the sum and difference (RF \pm LO) IF signals. A frequency-selective circuit will determine which one gets through to the rest of the circuits. One popular output circuit is a low-pass filter (Figure 4) that will pass only the difference signal. Alternatively, a high-pass filter will pass only the sum signal. This circuit allows considerable latitude, so long as the desired output frequency is within the passband of the filter. For specific IF frequencies (e.g., 455 kHz, 10.7 MHz, 8.83 MHz) used in receivers, a tuned bandpass filter circuit is needed.

A Useful DBM for the Workbench

Like many amateurs who have an electronic workbench in the basement laboratory, I have a goulash collection of signal sources bought new, bought used at hamfests, home-brewed, or obtained from goodness knows where in my 33 years as a ham. In order to obtain certain specific frequencies, however, I sometimes have to resort to using a DBM. Photo A shows my "test DBM." It consists of a Mini-Circuits SRA-1-1 mounted in an ITT/Pomona Model 2417 box. The cir-

Photo A. DBM packaged for use on testbench.

cuit is the same as Figure 3, except that for stability I placed 1 dB Mini-Circuits' fixed attenuators in series with the RF, LO and IF ports. These attenuators keep the impedance stable, even when the source or load impedance is either not 50 ohms, or varies. The variation does not affect the SRA-1-1, but has affected some circuits that I've been working on. The added loss is reasonable for the stability gained.

By the way, my new book, *Receiver Antenna Handbook* (HighText Publications, Inc., 7128 Miramar Road, #15, San Diego CA 92121) is about ready for publication. Although it deals with receiver antennas, there is much material for ham operators as well. My other antenna book, *Practical Antenna Handbook*, is more in tune with hams, and is available from TAB/McGraw-Hill (Blue Ridge Summit PA 17294) for \$21.95 (use catalog number 3270).

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS 73 MAG Message Area #4. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 924-9343). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters 1 or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

We wish to announce that Roxanne Delmage VE3VON, and Craig Delmage VE3KKU, are the current QSL Managers for 9L3BM.

I recently purchased a Hallicrafter SX-111 and HT-37 (matching receiver and transmitter). I am looking for a manual and/or schematic for this 1960s equipment. I will pay for copies. Brian Angel, 825 1/2 Wilson Ave., Ames IA 50010. (515) 232-7817.

Does anyone know where I can get info on the duties and responsibilities of Merchant Marines Officers? I'll take books, tapes, or any other educational materials. Please write and let me know what you have and how much \$ you want for it. Ed Melanson, RFD #2, Box 510, Thomdike, ME 04986.

Help! I just purchased a Radio Shack Model 102 laptop, and I'm looking for software, hardware and publication sources. I could es-

pecially use ham software, a spreadsheet, modem cable, printer cable. Please write or call, Brent Putnam N8UBD, 12110 Mayfield Rd. #6, Cleveland OH; (216) 721-2019. Or e-mail to bwp2@po.cwru.edu on college internet.

Can anyone help me locate Brian Key N5LNL? This station is with the military somewhere in Venezuela, not at the call book address. N5LNL was my first CW contact but I cannot find the proper address to send QSL. If you have any information, please contact Gene Kohring N8QWM, 1647 Millville-Shandon Rd., Hamilton OH 45013-9611. Thank you.

Manual/Schematic? B&K 445, EICO 330, EICO 379, SEMCORE RC115, TS-888. Marvin Moss WAUXJ, Box 28601, Atlanta GA 30358.

Newly licensed Ham, permanently disabled, no benefits, seeking goodwill donations of Ham equipment and related items. If it works, I'll take it. No item too big or too small. Can repair if minor. Will reimburse shipping and postage. I am for the most part, a listener. Age and external appearance of equipment is not a factor if it is functional. Cornell Howard N8TOJ, 231 Fenwick Dr., New Carlisle OH 45344.

I am looking for the diagrams and user/service manuals for my surplus communications receivers: RACAL HF 1-30 MHz, Model 1220 DRG#41880/D Serial #1551; RACAL VLF Converter NC-RA-6337A, Serial #260; CEI VLF-354 1-600 kHz Receiver, Serial #7. I will compensate for Xerox/mailling. Yuri Dzyuba VE2XLT (ex UB5LT), 3150 Rosemont #15, Montreal PQ H1Y-1M5 Canada.

ID-8 Automatic Morse Station Identifier

Compatible with Commercial, Public Safety, and Amateur Radio applications. Uses include Repeater Identifiers, Base Station Identifiers, Beacons, CW Memory Keys, etc. Great for FCC ID Compliance.

- Miniature in size, 1.85"x1.12"x0.35"
- Totally RF immune
- All connections made with micro-miniature plug and socket with color coded wires attached
- CMOS microprocessor for low voltage, low current operation, 5 to 20 VDC, unregulated at 5mA
- Low distortion, low impedance, adjustable sine-wave output, 0 to 4 volts peak to peak
- Crystal controlled for high accuracy
- Transmitter PTT output (to key transmitter while ID is being sent) is an open collector transistor that will handle 80 VDC at 300mA
- Field programmable with SUPPLIED keyboard
- Confirmation tone to indicate accepted parameter, plus tones to indicate programming error
- All programming is stored in a non-volatile EEPROM which may be altered at any time
- Message length over 200 characters long
- Trigger ID with active high or low
- Inhibit ID with active high or low. Will hold off ID until channel is clear of traffic
- Generates repeater courtesy tone at end of user transmission if enabled
- Double sided tape and mounting hardware supplied for quick mounting
- Operating temperature range, -30 degrees C to +65 degrees C
- Full one year warranty, when returned to the factory for repair
- Immediate one day delivery

Programmable Features

- Eight programmable, selectable messages
- CW speed from 1 to 99 WPM
- ID interval timer from 1-99 minutes
- ID hold off timer from 0-99 seconds
- CW tone frequency from 100 Hz to 3000 Hz
- Front porch delay interval from 0 to 9.9 seconds
- CW or MCW operation

\$89.95 each
programming keyboard included

Whether you're an experienced packeteer or a newcomer wanting to explore packet for the first time, this is what you've been waiting for! Thanks to a breakthrough in digital signal processing, we have developed a tiny, full-featured, packet modem at an unprecedented low price. The BayPac Model BP-1 transforms your PC-compatible computer into a powerful Packet TNC, capable of supporting sophisticated features like digipeating, file transfers, and remote terminal access. NOW is the time for YOU to join the PACKET REVOLUTION!

TV Camera Lighting

The minimum light sensitivity of TV cameras has improved dramatically in the past few years. I used to have a few bright floodlamps in my shack in order to provide enough light for my old color TV camera. It worked great outdoors in bright sunlight, but was dreadful inside. It needed 50 lux minimum light level to produce a good image. The "lux" rating is a light level corresponding to one lumen per square meter (approximately the light produced one meter from a single candle).

Even some of the newer cameras still require some attention to the lighting in your shack to come up with a decent image. Until now, TV cameras that were more sensitive than your eye were unaffordable.

The GBC CCD-200

I recently obtained a new offering from CCTV Corporation, 315 Hudson St., New York, NY 10013; (800) 221-2240, (212) 989-4433. Their new model CCD-200 B/W TV camera has some eye-opening specifications. This camera is somewhat smaller than a pack of cigarettes, has an automatic electronic shutter and includes a built-in microphone. The most amazing parts of it are the light sensitivity rating of 0.02 lux and the special \$204.50 price for 73 readers!

I first tested out the camera in a room with somewhat dim lighting: just one table lamp. I was amazed to find that everything in the room appeared brighter on the TV screen than it appeared with my eyes. I pointed the camera through a doorway into a dark room; the camera picked up objects that I could barely even see. The resolution was excellent (425 lines) and the microphone worked well. The wide range of the electronic shutter allowed me to look at the darkest portion of the room and compensate quickly when I pointed it directly at the lamp. You can even point this camera directly at the sun without ill effect (something you couldn't do in the old days with vidicon tubes).

Build Your Own Nightscope

I noticed that the CCD-200 was very sensitive to the infrared spectrum. It could detect the hot tip of a soldering iron, see blood vessels underneath my skin and see the pulsing infrared output of my VCR's remote control (invisible to the naked eye). I turned out the light, and found that the output of the remote control could illuminate a completely dark room when viewed through the TV camera.

I've always dreamed of owning my own Nightscope. It would be a real thrill to actually see in the dark.

A Nightscope uses a high-intensity infrared (IR) source to illuminate the scene and an IR-sensitive detector/light amplification scheme that views the area. It's all a very complicated and expensive affair occasionally obtainable through military surplus outlets.

The prospect of building my own Nightscope prompted me to run down to my local Radio Shack and browse through their LED section. I found an appropriate candidate in their high-output infrared LED (model #276-143b). I grabbed a handful of these and headed back home to the workbench. I mounted two of these on a breadboard, along with a current-limiting resistor for each LED (see Figure 1). Just attach the LED board to the power supply you use for your TV camera. For a 9-volt supply use 270-ohm resistors; for 12 volts or more use 470 ohms. Each LED draws about 25 milliamps.

I put the LED board into a small plastic project box and attached it to the top of the CCD-200 with velcro. I switched off the room light and turned on the TV camera/infrared LED system. I was amazed! It was as if the two LEDs were headlights illuminating whatever I pointed the camera at. Even though I was sitting in total darkness, I could clearly read labels and see objects up to six feet away on my TV monitor. To make sure that my TV set wasn't providing any illumination, I checked out the TV camera/LED system in a dark

hallway with the same results. The only visible indication that the LEDs are operating is a very dim red glow if you stare directly into the tops of the LEDs in a totally dark room.

To light up a larger room, you may want to add more LEDs to the system, but I found that even just one LED worked fairly well.

To make a portable Nightscope, just add a small portable TV monitor (such as the Radio Shack Pocketvision 26, RS# 16-163) and a battery pack; you can now literally see in the dark.

Although it is a visible light source, you can really light up a room with one of the newer jumbo red LEDs. A good one is the jumbo 5000 (Radio Shack# 276-086).

Security Applications

The security applications of this system are intriguing. You can mount the CCD-200 and the LED array in your repeater site, your ham shack or your clubhouse and observe any intruders via an ATV link without their being aware of the camera (after all, everything will appear totally dark to their eyes). If the intruders use a flashlight, the whole room will light up like it was broad daylight.

You can have the infrared ATV link (and VCR) come up whenever a security motion sensor (or magnetic window/door sensor) is activated. Instead of your normal ATV repeater ID, you'll have a bird's-eye view of the intruders.

Photo A. The CCTV Corporation CCD-200 low-light level B/W TV camera.

Figure 1. An array of high-output infrared LEDs mounted above the CCD-200 TV camera will provide enough illumination to light up a small room. Since the output is all in the infrared spectrum, the room will appear completely dark with the naked eye. For 9-volt operation use 270-ohm resistors; for 12 volts use 470 ohms.

GET-TECH

GET-TECH has released its digital voice recorder, AUDIO Q218. This unit will record up to 218 seconds of speech. With four se-

lectable sample rates, up to eight different variable-length messages may be stored. Two separately adjustable audio outputs are provided. One high-level output will drive a speaker to 400 mW; the other may be used for output to an external amplifier or transmitter. An on-board regulator allows use from 8 to 15 VDC. Also included is an open collector output for keying a transmitter or external device during playback. The 2.5" x 2.5" unit comes fully assembled and tested, including battery backup and 4 meg RAM.

The AUDIO Q-218 is priced at \$149, plus S & H. For more information, contact GET-TECH, 201 Riley Road, New Windsor NY 12553; (914) 564-5347. Or circle Reader Service No. 203.

GRE AMERICA

GRE America has introduced GINA, Global Integrated Network Access, a wireless data transceiver that transmits and receives data at rates up to 128K baud. GINA eliminates the expense, hassles and restrictions of wire connections, while providing reliable data communications. It utilizes spread spectrum technology, which is highly immune to interference. GINA can be incorporated into a wide variety of applica-

Hamtronics, Inc. has published their new "January 1993" catalog, which contains 40 pages of kits and wired units for amateur radio, two-way shops, scientific and industrial radio users, and OEMs. It features two new products: a digital voice recorder and a low-cost DTMF controller. The DVR-1 digital voice recorder may be used as a voice ID for repeaters, contest CQ caller, or radio scratchpad. It records up to 20 seconds of real voice audio in one or multiple message segments and plays back through a repeater or small speaker.

The TD-4 DTMF controller provides one latching output based on four-digit commands to turn any circuit on and off. It was

HAMTRONICS

designed especially for use as a selective calling unit to be used with any receiver or transceiver to allow the speaker to be muted until someone wanting to call you sends the appropriate DTMF command to open the speaker.

These new products are added to the selection of VHF and UHF FM transmitters, receivers, power amplifiers, converters, preamps, repeaters, DTMF controllers, autopatches and digital radio modems which Hamtronics has manufactured for over 30 years. To receive a copy of this new catalog, contact Hamtronics, Inc., 65-F Moul Road, Hilton NY 14468-9535; (716) 392-9430, Fax: (716) 392-9420. For foreign mail, please send \$2 to defray postage.

PAKTEK INC.

PAKTEK Inc. is now offering the TOOLPAKS product line. The TOOLPAK original is a backpack tool organizer that secures over 100 of your most needed and important tools; the FANNYPAK is a convenient way to carry those few tools you just can't be without. Perfect for Field Day or remote locations, TOOLPAKS eliminate chasing down tools, keeping those days in the field fun and exciting. FANNYPAK has room enough for your portable and all the extra

batteries, leaving both of your hands free. Made of durable abrasion- and puncture-resistant Cordura, the TOOLPAKS haul like a pack and open like a zippered file cabinet, keeping you organized and helping you work more efficiently.

For prices and more information, contact PAKTEK Inc., 7307 82nd St. Ct. S.W., Tacoma WA 98498; (800) 258-8458, Fax: (206) 589-1091. Or circle Reader Service No. 201.

tions, including automation, data acquisition and control, security systems and wireless network systems, plus other industries where remote or point-to-point data transmission is necessary. Because GINA utilizes spread spectrum technology, information can be sent transparently, penetrating

walls, floors, ceilings and concrete, while still maintaining clear data transmission.

For the price and more information, contact GRE America, Inc., 425 Harbor Blvd., Belmont CA 94002; (415) 591-1400, Fax: (415) 591-2001. Or circle Reader Service No. 202.

J-COM

j-COM has introduced a line of transceiver control computer interface cables designed to interface personal computers with all receivers and transceivers which have the ability to be controlled over a serial TTL link. The j-COM interface cable requires no external power supply. The unit requires only 3.5 mA of total power for ICOM and Yaesu models, and 6 mA for Kenwood. Removing the external power supply and its associated cables significantly reduces the susceptibility of the interface to RFI from the transmitter. Emitted RF noise is also reduced. The entire interface has been sandwiched into the shielded hood of a DB-25 connector compatible with the serial interface

assembled and ready to plug in. All four are priced at \$54.95, plus \$5 S & H. j-COM provides a 30-day money-back guarantee and a 90-day parts and labor warranty. Contact j-COM, Box 194, Ben Lomond CA 95005; (408) 335-9120, Fax: (408) 335-9121. Or circle Reader Service No. 205.

of most PC compatible computers. j-COM also supplies an optional DB-9 to DB-25 adapter for use with computers using the smaller size "AT" connector. Because the interface is a direct replacement for the manufacturer's own units, it is fully compatible with all rig control software.

The four models of interface cable come completely

A.S.A.

A.S.A. has introduced a product ideal for new hams—an affordable 2 meter colinear base station antenna with unbelievable gain. The model 9209 is made up of four parts and takes approximately 10 minutes to assemble. The master part is a six-foot vertical fiberglass hand-wound whip covered with heavy black heat-shrink with a 3/8-24 thread ferrell (double 5/8 wave over 1/4 wave). At the top is a three-foot stainless steel whip that is inserted one inch into the top of the whip. At the bottom is a double U-bolt aircraft aluminum bracket that fits up to a 1-1/2" mast with a 3/8-24/50-239 brass connector for your PL-259. The fourth part consists of three 45-degree aluminum radials, 21" long, attached underneath the bracket with screws. The total height after assembly is 10-1/2 feet.

The model 9209 is priced at \$32.43, and will be sent UPS within the continental U.S.A. for \$4 S & H. For more information, contact A.S.A., P.O. Box 3461, Myrtle Beach SC 29578; (800) 722-2681. Or circle Reader Service No. 204.

PERIPHEX

Periplex has announced its longer operating time, high capacity, lower cost batteries for the Alinco DJ-580 hand-held radio. The EBP-22S (12 volts, 800 mAh) offers a 15% increase in operating time at high power, while the EBP-24S (7.2 volts, 1500 mAh) offers a 200% increase in operating time at low power. Both batteries are 3" tall. They are completely compatible with the Alinco EDC-24 and EDC-34 chargers.

The EBP-22S is \$65 and the EBP-24S is \$62. All battery packs include overcharge and over-temperature protection, short circuit protection, and a one-year warranty. For more information, contact Periplex, Inc., 115-1B Hurley Road, Oxford CT 06478; (203) 264-3985, (800) 634-8132. Or circle Reader Service No. 206.

ONE ANTENNA — ALL VHF AND UHF BANDS!

CLP 5130-1
LP YAGI BEAM
50-1300 MHz
CONTINUOUS COVERAGE

One antenna does it all!

The CLP 5130-1 covers 50, 146, 222, 440, 902, 1296MHz Ham bands, VHF, UHF, 800MHz Public Service bands, Military, Aircraft bands, even complete Television and FM broadcast band coverage!

- * Outstanding performance with high forward gain, VSWR below 2.0:1 over entire frequency range!
- * Compact and lightweight, all aluminum design, multi purpose horizontal or vertical mounting.
- * Extra strong, commercial grade construction withstands the worst weather for unsurpassed reliability.
- * Can pass as a conventional TV antenna! Perfect for apartment dwellers, those with limited space or antenna restrictions.
- * **Attention Future Hams:** High performance, continuous coverage scanner reception now, all band transmitting beam ant. when you get your ticket!
- * Also available: Create model CLP5130-2 LP Yagi Beam with continuous 105-1300MHz coverage in a smaller size.

If you could only have one antenna for complete VHF/UHF coverage, this would be it!

Our New COMMUNICATIONS DECODER Is A MUST For All Serious FM'ers!

**Introductory
price: \$199**

THE MODEL CD-1 DECODES & DISPLAYS:

- **104 DCS CODES (Digital)**
- **50 CTCSS TONES (Analog)**
- **16 DTMF DIGITS (Touchtone)**

The CD-1 reveals everything you need to know to operate any open repeater or phone patch. Simply connect the CD-1 to your base, scanner or mobile radio.

When someone uses a system, the CD-1 decodes and displays the CTCSS or DCS code and in addition any DTMF codes that were used to control the system. (Including phone patch access codes and the phone number dialed). DTMF sequences are stored and automatically replayed just in case you missed something important. Use the CD-1 to learn police and fire codes too!

NEVER SAY DIE

Continued from page 4

the channel is occupied, just as a phone or CW op would, and then wait for a possible response, which would put the relay on hold, we might be able to avoid much of the QRM which blind transmissions could incur. Indeed, if the relay station did get a response it should be programmed to keep track of the activity on the frequency and sense when it has ended so it can send another query, checking for any possible new interference.

On 20m and higher bands it's normal not to hear both ends of a contact, so an automatic relay station should be able to do more than merely check for any received signals. It should be intelligent enough, via its software, to avoid interfering when only one side of a contact can be heard. Perhaps we need to agree on some protocols to help simplify this problem.

At any rate, I'm glad cooler heads prevailed and that another escalating brouhaha may have been avoided. We need peace, not war within our hobby.

ARRL Caves In

The uproar over the ARRL's proposed ban on automated packet on HF was so furious that the League was forced to back down. Indeed, it got so bad that disgusted packeteers were beginning to talk seriously about forming

their own national society. Well, when an organization gets that far out of step with a large block of the membership, something has to give. And give it did.

A hasty meeting of the ARRL digital committee, plus most of the board of directors and the executive committee, was held during the ARRL National Convention in Los Angeles. Faced with insurrection, they had little choice but to reverse the board of director's July decision. The details of a new proposal which will allow automated packet still have to be agreed upon, but it looks as if the board capitulation may have defused a very nasty situation which could have seriously hurt League membership.

Indeed, packet operators aren't soon going to forget what they interpret as an antagonism to packet on the part of the ARRL's digital committee and the board. Hopefully the directors have learned a lesson and will be twice cautious before again trying to stop packet pioneering and network development.

With packet operation being virtually the only contribution amateur radio has made to communications technology in a generation, we need to give our packeteers every bit of help we can. We'd like to see HF packet develop dependable 9600 baud systems. We'd like to see them design circuits which will give perfect copy through interference, static, fading and so on. None of this is going to come easily.

It is unfortunate that we seem to have so many extremists in our hobby. The cries that unattended HF packet stations will be jamming our HF bands with unintentionally triggered transmissions is as ridiculous as the predictions that the no-code license would turn our bands into CB-like disasters. We seem at times to have an inexhaustible supply of reason-challenged loud mouths.

Packeteers, stick to your guns and make those fogies on the ARRL board stop trying to be clogs in the wheels of progress.

Making Money

A 52-page catalog from Home Automation Labs, 5500 Highlands Parkway, #450A, Smyrna GA 30082-5141, reminded me that I've had a few more surly letters from retired hams worrying about not having enough money. Get off your rocking chairs and get busy. I mentioned recently that \$10 bills are just hanging out there, waiting to be plucked. Well, presuming you're not a total washout as a ham, you should have the technical expertise to help people set up security systems in their homes, offices, warehouses and so on. Plus you can help them automate their homes.

A retired chap near my home put up some notices on the local supermarket bulletin boards announcing he was in business repairing VCRs, TVs and hi-fis. His come-on was a free estimate of

the cost of repair. My wife immediately loaded up the car with a few VCRs and a CD player which had been waiting for me to have time to set up a workshop and then see about fixing 'em. I guess, after year or so of excuses, she figured there might be a better way. Well, this chap, within days of putting out his shingle, is up to here in stuff to fix. His estimate is free. His prices are fair. Plus he brings good old Yankee thrift to the table, getting needed parts from truly defunct VCRs.

If you want to make money all you have to do is look around and see what people need done. It may be handyman work around their homes, feeding their pets while they're on a trip, or you might, as my wife did, find such a need for baby-sitting that you organize a baby-sitting service, hiring dependable women and scheduling for them.

Unless you're a complete zero you must have developed some skills. So where can you market them? You can offer services to smaller companies as a consultant, thereby helping them avoid medical coverage, which often adds around 30% or so to the payroll. Very few companies don't need extra help, it's just that it is so much trouble interviewing people and hiring them that they tend to avoid it. So talk to the boss and find out what problems he has. Then show him how you can help solve his problems for a fraction of what he's losing by letting things go.

QSO Tutor®

Study Aid for the Amateur Radio Exams

Mac IBM®

Consider the rest, then buy the best!

- Runs on IBM compatibles or Macintoshes
- Programs are available for Novice, Technician, No-Code Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radiotelephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pools, or study questions automatically selected by the program from your weakest areas.
- Questions current as of October 1992
- Includes full screen graphics, explanations on appropriate questions and, on the IBM version, a pop-up calculator.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or printed with graphics on Epson/IBM or Macintosh printers.
- Public Domain Morse code tutor is included on request at no extra charge.

New - No-Code Tech. Package!!

Compare the features - No other theory tutor contains the entire question pool, explanations, graphics, progress analysis and automatic concentrated study where you need it.

"Great Programs - I passed the advanced and extra licenses both in one morning! After 12 years as a general. The sample test portion really got me going! Nice you in the pilot!" **WRRYJF**

"As far as I am concerned, there is nothing like the QSO Tutor program. I have tried another and believe me, there is no comparison." **KAZZBE**

"The most advanced program I've used... Graphics are extraordinary... This program should be your first consideration." **Gordon West - Worldradio**

"Do I recommend the QSO Tutor? Heavily, yes! It really motivated me and it's a great way to test my progress. The learning is a natural by-product of the fun I am having." **Jim Bink - 73 Magazine Review**

Also Available:

QSO Controller®
The ultimate companion for controlling late model Kenwood rigs.

- Full mouse driven graphical user interface.
- Controls all functions of TS-950, 940, 850, 811, 711, 450, 440 and 140.
- Includes integrated logging, custom scanning, extended memories with annotation, real time S & multi-meters on screen, CMT, in/out-of band conditions by license class, and much more.
- Available for Macintoshes and IBM compatible (EGA or VGA only)
- Call or write for details

Say, have you got a shirt? Well then you're all set to launch a small ham business of some kind. The shirt is what you'll lose. Every now and then I hear someone sounding off about ham companies getting rich off us hams. When I hear that I know I'm faced with a blowhard fueled by massive ignorance. If you want to sell to hams, figure you're doing it as a hobby and make sure you've got a steady outside job to cover your losses.

I almost got into the ham business back in 1946. I'd designed a fantastic little 2 meter transmitter . . . a pair of miniature tubes with a long lines tank circuit and grid modulation. It worked like a charm, even in the trunk of my car. Bill French W2NYC and I talked with Millen rep John de Blasi about their making it. Millen wasn't interested. I was just out of the Navy after WWII and was going back to college in a few weeks, so we decided it wasn't a good time to start manufacturing rigs. In retrospect, perhaps we should have so we could have shared in the catastrophe that hit the ham industry in 1964 when it was almost totally destroyed by the League. Even the mightiest fell . . . including Millen, National, Hallicrafters, Hammarlund and so on. There were no survivors of any size.

On the other hand, going back to college turned out to be a miserable waste of my time. Two years blown to hell, with nothing really to show for it,

and very little of any value learned. I sure wish there had been someone around to put things into perspective for me.

Well, back to making money. Most of the businessmen I talk with have plenty of jobs open, they just don't know how to find the people they need. I had lunch with a chap who's working on solid prototyping computers. If you're not aware that there are now printers which will make solid objects you haven't been doing your homework. And if you're not keeping up with what's going on in technology, how valuable are you as an employee?

Desktop manufacturing is going to be a whale of a business in a few years, so this is the time to work with a small firm experimenting with prototypes and come up to speed. In a year you should be able to name your price if you get busy and become an expert.

This new field needs a publication to help it grow, but I'm too short of people right now to tackle it.

So tell me again how you're short of money. Tell me about being out of work. Tell me about not being able to afford that new rig.

Starting Education From Scratch

For starters we know our present educational system is failing us. Worse, we know that unless we make some major changes we're going to be sentencing our children and grandchildren

to a second-class quality of life. Either we turn out the educated and skilled workers needed to do high-tech manufacturing or we're going to continue to see our standard of living sliding.

Having done a hellacious amount of research on the situation, my next priority is to put everything I've learned together into one big report. Then I have to see how I can get the changes started.

Since I'm solution-oriented, my report will tend to emphasize proposed changes rather than just citing what's gone wrong. Unless you've been living the life of a mushroom you're well acquainted with how bad things are. And you probably have read, heard or seen on TV reports on how poorly we're educating our children.

My approach to the educational process is to break it down into child development periods. I'm arbitrarily dividing education into eight age groups. I think you'll see the sense of this as we progress. I think you'll agree that we all tend to learn things differently at different ages. We can't deal with a one-year-old kid the same as we do an adolescent. And ditto someone in their twenties vs. someone in their sixties.

Age #1

You're probably expecting me to start with kindergarten. No way. By the time kids are five years old around 80% or so of their life's patterns are already

fairly firmly set. Nope, we've got to start much earlier. Much, much earlier. Hold your chair and don't laugh . . . we're going to start with conception. I think you'll agree that I'll make a very good case for this. So let's assign Age #1 to the nine months between conception and birth. As you'll see, this is a surprisingly active educational period of life.

As you understand more about the importance of this time, you're going to understand why we need to radically change some motherhood behavior during this critical period of life.

Now, before I can help you understand how education takes place during the prenatal months, I have to go back to some fundamentals of all life. I don't want you to have to take my word for the importance of the prenatal period, I want you to understand why this time is so critical. And from that understanding you'll be able to figure out for yourself what changes mothers need to make.

In my October editorial I explained how all living organisms obey the most fundamental of all laws . . . self-preservation. I explained that all life has a stimulus-response mechanism built in which is designed to warn of possible harm. Trees have this and respond to danger by generating chemicals to ward off invasions of insects or to fight off other plants. In humans pain is our warning medium. Pain tells us when

MOSFETS

For the last year or so I have been playing with a remarkable solid-state device: the power MOSFET (MOSFET is short for Metal Oxide Semiconductor Field Effect Transistor). The power MOSFET was introduced by Siliconix, Inc., in 1976. I find what these devices are capable of doing absolutely amazing. More and more of them are finding their way into my QRP projects.

Figure 1 shows a schematic drawing for a power MOSFET. The three main leads to the power MOSFET are: gate, drain and source. Most power MOSFETs are "N" type devices, but there are several different types being made as "P" type devices. Notice the diode connected between the source and the drain leads. This diode is part of the internal workings of the power MOSFET. The internal diode has the same current ratings as the MOSFET.

There are many, many specifications for the power MOSFET, but we need concern ourselves with only four. First, there is the continuous current for the drain, commonly called I(D). The drain current is for a specific junction

temperature and at a specific gate voltage.

The second specification is the gate on resistance, known as RDS(on). This is the resistance the FET shows when it is turned fully on. This resistance is measured between the source and the drain.

Third is the voltage of the MOSFET. As a rule, as you lower the RDS(on) the voltage rating of the MOSFET is also lowered. In other words, a power MOSFET with an RDS(on) of 0.028 ohms may be rated at a voltage of 50 volts. On the other hand, a power MOSFET with an RDS(on) of 0.018 ohms may have a voltage rating of only 30 volts. They make power MOSFETs to handle up to several hundred volts. However, as the voltage increases, so does the RDS(on) resistance. With the higher voltage, you can have an RDS(on) of several ohms.

The RDS(on) resistance is also dependent on the temperature of the MOSFET junction. Most power MOSFETs have a positive temperature cure. As the power MOSFET heats up, the RDS(on) resistance increases. This increases the voltage drop across the device and causes even more heat to be built up.

The fourth specification is input ca-

pacitance. The capacitance varies with the die size of the power MOSFET, but it generally ranges from 30 pF to 3,000 pF. This capacitance must be taken into account when designing amplifiers. The extra capacitance will hold the gate on a bit longer while doing high speed switching. A special driver circuit must be used to ensure proper gate turn-off times.

Using MOSFETs

The power MOSFET makes a perfect high-side switch. Unlike the bipolar transistor with its 0.7-volt drop, a single high-side MOSFET switch can have a resistance of less than 0.010 ohms! You can easily run 30 amps of current through a high-side power MOSFET switch and dissipate only 9 watts. If you run high current like that through a transistor, you'll have a real heat problem on your hands. By adding more power MOSFETs in parallel, you can drop the RDS(on) resistance to extremely low values. I've run 30 amps through several power MOSFETs and have a calculated loss of only 2 watts!

To use a power MOSFET as a high-side switch, you will need to build a voltage pump or some other type of gate driver. A voltage higher than the voltage being switched is needed to turn the MOSFET on for high-side switching. In a typical 12-volt system, a gate voltage of +20 volts will be required. Most MOSFETs have a limit as to the maximum voltage applied to the gate. This is normally +20 volts maxi-

mum. Voltage higher than this may cause the insulator surrounding the gate to be pierced, destroying the MOSFET. This is known as the breakdown voltage.

A voltage pump can be as simple as an oscillator and a voltage multiplier circuit. There are several different types of MOSFET gate drivers available. These are little more than a voltage pump and associated control circuitry, all contained in a single 8-pin DIP IC. Right now, these ICs are somewhat expensive and hard to obtain. Figure 2 shows a simple voltage pump. Notice that it consists of a single CMOS IC and some diodes. Two stages of the IC are configured as an oscillator. With the values shown, the oscillator runs at about 300 kHz. When the control line is pulled low, the output of the oscillator is coupled to the two 0.01 capacitors and then into the voltage multiplier. The output is about +22 volts. This voltage pump works up to several kHz. It's a bit slow to turn off and therefore may add some distortion to the output if you try to switch it off and on at a rate of over 20 kHz.

A zener diode on the output of the voltage pump will protect the MOSFET's gate from over-voltage. This is but one version of a voltage pump. I've used just about every configuration with just about every IC known and have always come up with something that works. A 555 timer in a stable mode makes a great voltage pump.

You can parallel-power MOSFETs

MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.

The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator!

Multiple Independent Repeater control
Up to 5 Duplexed Links
Up to 4 different Remotes
Recorded Natural Speech Telemetry
Programmable Macros
Connect / Disconnect multiple Ports
Internal Receiver Squelch processing

Easy servicing
Integrated Autopatch
Expand at any time
Programmable Scheduler
+10v to +14v Supply
Standard 5.25" Rack Mount
Card-Cage design

Figure 1. Schematic drawing for a power MOSFET.

without too much trouble. You don't need to worry about picking out a "matched pair" as you do with transistors.

In theory, a perfect switch would have zero resistance when on and infinite resistance when off. A power MOSFET comes very close to a perfect switch. And indeed, a power MOSFET makes a very good switch. Power MOSFETs are used in a variety of switching applications, mainly in switching power supplies. The new compact fluorescent lights use high voltage power MOSFETs instead of a magnetic core ballast.

A power MOSFET is a voltage-controlled device unlike the transistor, which is a current-controlled device. The drive requirement for a power MOSFET is easy to obtain. For simple switching circuits, a gate voltage of +10 volts will turn the MOSFET fully on. One of the best traits of the power MOSFET is the ability to be rapidly switched on and off. This makes the power MOSFET a very good candidate for RF switching and amplification. A power MOSFET amplifier can be operated in Class A, AB, B or C. The power MOSFET is particularly immune to high SWR damage.

If all of this is true, then why have we seen so little about the power MOSFET? Well, price is one thing that has kept them from use. However, the price of single-lot power MOSFETs has fallen to the point where you can now buy them for under two dollars. For MOSFETs with a really low RDS(on), the price is still a favorable \$4-\$5 each.

For use in RF applications, most power MOSFETs like to see a source voltage of +28 volts. While it takes no more effort to build a 28-volt supply than to build a 12-volt one, a 28-volt transceiver is much harder to operate in the field on batteries. When used with a commercial power line, that restriction does not apply. In fact, many of the newer transceivers today use high voltage (+28 volts) power MOSFETs in the power amplifier stages. The higher supply voltage gives them a better efficiency and a cleaner output than a bipolar transistor. Japan Radio has recently placed on the market a 1 kW solid-state amplifier using high voltage power MOSFETs running with a +60-volt supply. The higher voltage

also allows the designer to use a smaller power supply. It's much easier to generate +60 volts at 50 amps than +12 volts at 250 amps.

Because the power MOSFET is a high impedance device, it can become unstable when used in certain designs, and God knows, I've fried many a power MOSFET in my workshop. I've blown the tops right off the case, leaving only the leads left soldered to the PC board.

They will oscillate on their own for no apparent reason. Even when used as a switch, the wiring to and from the power MOSFET as well as the layout of the PC board must be taken into account. One designer I know who is working on a high power (2 kW) sine wave inverter told me to add ferrite beads to the gates of each power MOSFET to keep them tame. Lay out your circuit for a power MOSFET just as you would any RF device, even if you're not using the MOSFET in an RF application. This includes good grounding and plenty of bypassing, especially on the gate lead. All leads must be as short as possible. No clip leads are to be used here.

What's Available?

Here are some typical power MOSFETs you can buy. The IRF511 is available from Radio Shack. It goes for about \$2 and has an RDS(on) of 0.5 ohms at 4 amps of drain current. It's not a real "hot" MOSFET as they go, but you'll find it hanging on the pegs at the local "shack." For a much better device, use an IRF531. This MOSFET is about 10 times better than the 511 and has an RDS(on) of about 0.05 ohms at a drain current of 15 amps. Both the 511 and the 532 come in a standard TO-220 case style.

For even more current and a lower RDS(on), try the IRFZ30 and the IRFZ42. These MOSFETs have a drain current of over 50 amps! The RDS(on) is a scant 0.028 ohms. Although much harder to find, the Siliconix SMP60N06 has a drain current of 50 amps and a RDS(on) of only 0.018 ohms. Siliconix also makes a 30-volt MOSFET with an RDS(on) of 0.010 ohms. That's 10 milliohms of resis-

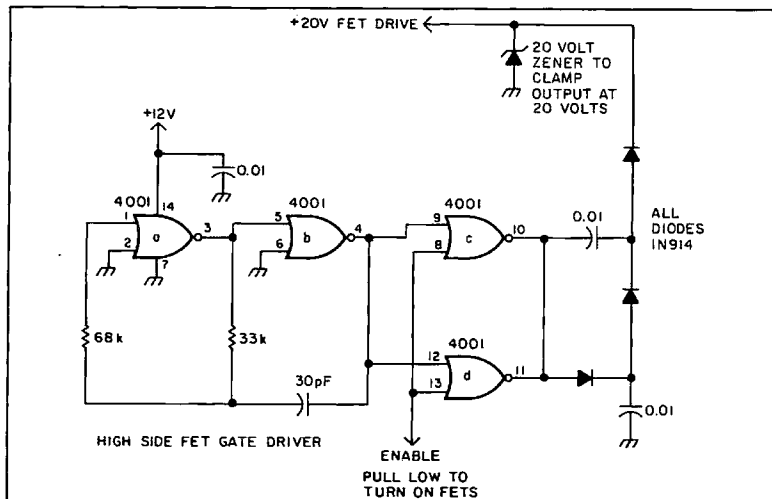

Figure 2. Simple voltage pump for a high side FET gate driver.

tance! Again, these devices come in the standard TO-220 case. You can find these MOSFETs listed in both the Digi-Key catalog and the Mouser Electronics catalog. Neither company carries the Siliconix devices.

Because the TO-220 case is electrically hot, when mounting the MOSFET to a heat sink you must insulate the device from the heat sink. You can use any of the TO-220 mounting kits on the market. Radio Shack sells one for under a buck.

I have found that even though the

device may be rated at 50 amps of drain current, getting that much current in and out can be a real engineering task. It's better to use two or more MOSFETs in parallel to split up the current instead of using one MOSFET.

Next month I'll have some circuits using power MOSFETs. Also, in the coming months I'll show you how to build a solar charge controller using pulse width modulation by way of power MOSFETs. Stay tuned—there's a lot of good stuff coming up here in the "QRP" column.

ANY RIG—ANY ANTENNA AUTOMATICALLY SMARTUNER™

Let's get frank about HF antennas. Most hams try to put resonant antennas up for every band. For those with the room, great! But for the rest of us, limited to perhaps a single long wire or some other compromise antenna, the SGC SMARTUNER is the ideal solution. Its onboard computer selects exactly the right inductance and capacitance from more than one half million possible combinations. Then it remembers the setting so your rig will retune in 10 milliseconds. It's waterproof, too, built to exacting commercial standards.

SGC Building, 13737 S.E. 26th St., Bellevue, WA 98005 USA Fax 206-746-6384 Tel. (206) 746-6310

The Last Micro

Hi, folks. I think we're finally ready to wrap up our Micro Power mini-series. We've covered what micros are, how they work and what can go wrong. Let's look at some of the other circuits sometimes used with microprocessors and microcontrollers, and at the problems they can cause.

Reach Out and Scan Someone

Some rigs just have too many buttons and switches for one chip to read them all! This can be true even when the switches are multiplexed. In such big radios, input/output (I/O) expander chips are used. These are nothing more than data selectors or multiplexers. In this case, though, the term "multiplex" has a slightly different meaning than it does when applied to switches. What these chips do is place the binary value of some of their input pins onto their output pins, with the computer selecting which input pins are to be examined. For instance, there may be 16 input pins and four output pins. By sending a code to the multiplexer chip, the computer can check all the input pins in groups of four.

Another technique sometimes used is data encoding. Here, the 16 input pins are simply converted into a four-bit word. (Remember, four bits can specify 16 different states.) The computer simply decodes the four bits to determine which button was pressed. The disadvantage of this system is that it can only tell if any one button

has been pressed. Multiple presses will cause an erroneous code. That is, unless the buttons are scanned first, as I described a couple of columns back.

No Response

If the radio won't respond to a button press, there are some clues to look for before you dig in with the scope. First, is it just one button that won't work? If all the others work, I'd suspect the switch itself. Check the voltage on both sides of it. If you see a pulse, then you know it's a multiplexed (scanned) switch. The pulse should appear constant on one side of the switch and come and go on the other side when you press the button. If you can't find the pulse on the

Getting Lost

If the switch is working, the signal must be getting lost somewhere on its journey to the micro. Unfortunately, that journey may be quite convoluted! If the I/O system is scanned, chip by chip, by the micro, the button press may be turned into no more than a tiny blip before entering the bitstream. It can be mighty hard to separate the blip you want from all the other blips because everything is traveling on a common buss, just like in any computer system. Really, it can be next to impossible without a logic analyzer, or at least a dual-trace scope and a lot of luck.

A bad I/O chip is much more likely than a bad micro. Try this: Trace the switch back to the I/O chip. Now find the "chip select" pin. There should be a pulse on it. Trigger your scope on that pulse and then check the output pins, one by one, while you press and let go of the button. If you find an output pin with a pulse appearing or dis-

and there's no pulse, suspect the other chip, because it isn't driving the I/O chip. Of course, it may not be getting the signals it needs. Now you can see why it can be so maddeningly difficult to mess with any but the smallest digital systems. You can spend an awful lot of time going down blind alleys and buying chips you don't need.

Going Out

The same I/O techniques are used for LED annunciators and some other output signals, including those which actually control various parts of the radio. Remember, when you select the operating mode (AM, SSB, etc.), IF filter, etc., you are really telling the micro to select them. It interprets your request and sends all kinds of signals to various circuits in the rig. For instance, when you change bands, not only does the frequency synthesizer get set, but the various bandpass filter relays get set, too. Ever notice that tuning through certain frequencies causes a mechanical click from the radio's interior? That's a bandpass filter relay being tripped.

I/O failures can cause all kinds of strange symptoms. For instance, if transmit output power or receive sensitivity is way down only on a certain band, check that the bandpass filter relay is being set, and that the relay contacts are working. Also, many functions are switched with diodes, and a bad diode can make it look as if the I/O system isn't working properly.

In general, I/O failures are more common on the output side than the input side because many outputs are driving things, such as LEDs, which require substantial current. Some radios use buffer transistors to protect the chips, but many don't, and those can stress the chips to the burnout point.

Memories...

ROM and RAM can fail. When they

"Some rigs just have too many buttons and switches for one chip to read them all!"

other side, the switch is not making contact. In particular, that can happen with flat membrane switches, particularly if they've been exposed to bad environmental conditions such as liquids or prolonged cigarette smoke. If the switch is bad, you may be able to peel it apart and clean it if you're careful.

If you get DC on one side of the switch and nothing on the other side, try scoping the DC side while you press the button. If it goes to zero, the switch is working. If it doesn't, check the other side. If it rises, again, the switch is working. If there's no change, the switch is *not* working.

appearing when you press the switch, the I/O chip is good. If you can't find any change, the chip probably is bad. There's no easy way to be absolutely sure, short of trying a new chip. Luckily, many radios use standard I/O chips you can get from American companies. Some, of course, don't.

By the way, if there is no pulse on the chip select pin, check the schematic to see if that pin is tied high or low. In some simple systems it can be, particularly if there's only one I/O chip to begin with. Most likely, though, there are several chips being scanned. If the chip select pin is connected to the output of another chip,

do, the micro essentially has a case of Alzheimer's disease, and it acts accordingly. It may do strange things, such as write garbage to the display or refuse to tune properly. Usually, though, it'll just crash altogether and become non-responsive.

If the failed memory is inside the micro, the chip must be replaced. If the memory is external, you're in better shape because memory chips usually are a lot cheaper than micros. At least, RAMs are. ROMs are another story because they contain the manufacturer's operating program. Although the chip may only be worth five bucks, you may pay \$50 or more for a new one. You're paying for the software, not the IC!

Memories can fail in three ways. First, the chip can die completely, with all of its outputs stuck either high or low. This is the most common type of failure, and the stuck outputs can pull down (or up) the entire buss, making it very hard to find the guilty chip without pulling them, one at a time. In the case of soldered-in chips (which most are), the likely damage to the PC board from removing all those chips is so severe that you would be foolish to try it.

Another failure mode causes just one of the chip's output lines to get stuck. That will cause one of the buss's lines to get stuck. If you see activity on all the buss's lines except one, suspect this kind of failure. Try

disconnecting from the board the suspect pin of each chip, one by one. Be sure to reconnect them after each try so that only one is disconnected at a time. Of course, the computer won't work properly in that state, but if the stuck buss line starts showing pulses again, you've found the bad chip.

The weirdest failure mode occurs when only one memory cell goes bad. In that state, everything continues to work, but it just doesn't work. Data gets scrambled and the computer mal-

of cooling spray will really help here. By the way, there now are ozone-friendly cooling sprays available. I have a can, and it is odd stuff. It works pretty well, but it is very heavy and it literally "falls" out of the can! It looks quite strange when you spray it. Also, it tends to ruin plastic, so keep it away from the outside of the radio.

If you have a thermal problem, spraying the chip will not directly return the computer to operation the way it would in an analog system. By the

works fine for a while, then it goes nuts! The display gets weird and the rig won't work. If I turn it off and on again, it works for a while, then it does the same thing. Clearing all the memories has the same effect. Any ideas?

**Signed,
Scrambled**

Dear Scrambled,

This is very appropriate to our current topic. Your rig's computer is getting trashed. This one's easy, though. If you remove the unit holding the speaker, you'll see a sealed metal box. Unscrew the cover and you'll see the "Digital-A" board. On it, there's one socketed IC, and that's the ROM which contains the rig's operating program. Early '940s often had this problem, and the solution is to pull the IC and put it back in, being sure to press it in all the way. (Be careful not to reverse the chip, of course!) Apparently, the heating and cooling cycle makes the chip work its way out of the socket over a long period of time. (My old Apple II+ had the same problem!) Later '940s had a wire soldered to the ground pin of the IC, and even later ones had no socket at all. I suspect yours is an older one, though, or this wouldn't be happening.

Well, I think that about covers the micros so, next month, we'll get into something new. See you then. 73 de KB1UM.

"Remember, most thermal problems are caused by bad connections, not bad chips."

functions. The problem may be as subtle as a wrong display digit or indicator light, or it may shut the computer down altogether! Trust me, you won't find this problem. If you suspect it, go find the shipping box. Luckily, this kind of failure is pretty rare. I've seen only two memory chips do it.

All Hot Up

These failure modes can be thermal, too. Generally, a chip with all lines stuck is dead and will *not* be thermal. But a single line can be working when the chip is cool and then quit when things warm up. A single bad memory cell can do the same. A can

time you spray the part, the computer's program is off in never-never land. The cure is to spray the chip and then turn the radio off and back on. If there's a reset button, that should do it, too. Remember, most thermal problems are caused by bad connections, not bad chips. Even if spraying a chip fixes the problem, check the connections to the board before replacing the part. Even if they look OK, try resoldering them. You never know, you just might save the cost of a new IC!

Now, let's look at a letter:

Dear Kaboom,
My TS-940 has an odd problem. It

Simulated Circuits—DSP High Tech in Your Shack

As most of you already know, one of the major components of a TNC or multimode controller is a modem. "Modem" is a compound of the beginnings of the words MODulate and DEModulate. It is the modem's job to turn digital signals—which consist of simple "on" or "off" information, unsuitable for transmission on an audio channel—into analog signals which are suited to audio transmission. Normally, the modem does its job with the help of analog filters. These are tuned circuits that react to the presence of the tones used by some particular communications standard. For example, packet radio running at 300 baud on HF uses tones at 2110 Hz and 2310 Hz to transmit data. So, to receive 300 baud HF packet, a modem needs filters at these frequencies. Keep in mind that this is meant to be a simple example to get the point across: As the data rate increases, the complexity of the modulation scheme follows, using other aspects of the signal, like its phase. The example given is called "FSK" for Frequency Shift Keying.

The idea is this: Until recently, if you wanted to receive a particular mode, you needed a modem specific to that mode, made of analog parts and somehow connected to your controller. While you still need a modem designed for each mode's unique properties, it no longer needs to be made of capacitors and resistors. How is this possible? Thanks to a technology—not new, though only recently affordable—called DSP (Digital Signal Processing). DSP is an application of computer technology that lets a hardware engineer design and implement an analog circuit in software. That circuit is a simulation of the discrete (individual analog component) version that functions precisely as if it were a normal analog circuit. This approach brings a number of advantages, with two being of particular interest to the ham.

Performance

Within their operational limits, digital filters can provide much better performance than analog versions. One of the reasons is the ability to precisely tune the behavior of the particular filter, even to the point of having it change characteristics to best suit the current situation. Digital filters can be created with characteristics unavailable in analog designs—such as the brick wall filter you will find in your CD player. This

filter is designed to completely eliminate any output above 20 kHz, and the digital version can have a very steep cutoff not possible in an analog implementation.

Flexibility

This is the part that will be near and dear to the hearts of those of you who have gone from RTTY to AMTOR to 1200 baud packet to 2400 baud packet—you get the idea—buying a new box for each mode. A DSP-based multimode controller just doesn't become obsolete—at least not for a long time. Why? Because the modems—those pesky parts that are different for each mode—aren't real, they're simulated by the DSP chip. This means

eliminate multiple interfering carriers with very narrow notch filters, built on-the-fly by the filter box itself—no tuning or adjustment. Imagine being able to have SSB QSOs on 40 meters again, at night! If this sounds like magic, well it is a sort of computer technology magic, but it works. This problem is ideal for DSP because of the nature of the interfering signal—steady and constant. What about problems with interfering impulse (ignition), or white noise, that don't share this convenient obviousness?

DSP can help here, too. The technique is just the inverse. Get this: The DSP filter listens to the signal, identifies the human speech by its characteristic properties (speech is not highly correlated like a carrier, but it does have specific qualities that separate it from noise and other signals), and builds a bandpass filter—again on-the-fly—that fits the speech. The effect is to filter out the surrounding signals that are interfer-

***"Within their operational limits,
digital filters can provide much
better performance than
analog versions."***

that a DSP-based unit only needs new software to operate in the latest and greatest mode. Finally, you can buy one box and stop.

Of course, modems are not the only use for filters in the ham shack. AF (Audio Frequency) and RF (Radio Frequency) filters that tailor the signal heard from an HF receiver are also vital to good operations, particularly on crowded bands populated with rogue broadcast stations—like 40 meters—or stations whose entire ham radio interest (it seems) is tuning up on top of other QSOs—commonplace on 20 meters. Traditional analog filters can help with these problems, but the limitations real world filter circuits place on them makes them far from ideal. For example, a good analog notch filter can eliminate much of a single interfering carrier—like the heterodyne from a broadcast transmitter, or a station tuning up—but they are difficult to tune and can only deal with a single interfering signal at a time. Enter DSP, perfectly suited to this problem. With a relatively simple DSP filter it is possible to adaptively (that is, on-the-fly) notch out interfering signals—automatically!

This is possible because of the highly correlated nature of a heterodyne type interfering signal. In other words, the signal is constant and regular—completely unlike the human speech that is carried by the desired signal. A DSP-based notch filter can automatically identify and

ing. The results of this process are not quite as miraculous as the notch filter but it works, dropping the noise by as much as 20 dB. There are some limitations to this technique, and it won't take a signal from the mud and make it louder than the S9+20 noise from the dirty power line insulator down the block. On the other hand, it certainly will reduce the user fatigue caused by listening to the noise surrounding the signal you want, and make QSOs on the HF bands less headache-producing.

What You Can Buy

Thanks to the general availability of low cost DSP chips, several manufacturers now offer DSP-based ham radio gear. These products fall into the two categories discussed above—multimode controllers and adaptive filters. Here's a list (fairly complete, but certainly missing a few) of what you can order today to get on the DSP bandwagon, and maybe reduce some of those heterodyne headaches.

Multi-Mode Controllers

DSP-1232 and DSP-2232
AEA (206) 774-5554
List Price:
DSP-1232 \$789
DSP-2232 \$999

The DSP-x232 series of data controllers from AEA are available now through dealers. The difference between the two units is in the number

of radio ports—one for the 1232 and two for the 2232. The DSP-x232 is based on the Motorola DSP56001 DSP chip, paired with a Zilog Z-180—which does the general purpose computing. The currently-shipping version of the DSP-x232 offers 10 modem programs for the DSP56001 stored in ROM:

- 300 baud HF packet
- 1200 baud VHF packet
- 2400 bps packet
- 1200 bps BPSK packet (satellite)
- HF RTTY
- Morse
- Facsimile
- FM SSTV
- 9600 bps (K9NG compatible)
- 1200/4800 bps ASCII (Satellite)

and dual port operation (DSP-2232) for 300/1200 or 1200/1200 baud packet, and RTTY-AMTOR/1200 baud packet combinations. There is 32K of DSP RAM which can be used to download additional modems into the unit. These future modems will be delivered by AEA on diskette, or be made available for downloading from a BBS.

DSP-12
L.L. Grace Communications
Products
41 Acadia Dr.
Voorhees NJ 08043
(609) 751-1018
List Price: \$695
RAM Expansion: \$99
A-to-D, D-to-A option: \$49

The DSP-12 from L.L. Grace is ideal for the experimenter. Along with its DSP56001 DSP chip, it sports a V40 (PC-compatible) processor on board. This means that programs for the box can be written in readily available PC-based languages with all of their associated development tools. With the 1 megabyte RAM upgrade option, the DSP-12 could be made into a stand-alone packet station with a sophisticated terminal program built-in, or a special-purpose communications device. Also available for the DSP-12 is an eight-channel A-to-D and DAC option which allows for all sorts of possibilities—including telemetry, voice recording and playback, and any other analog application that the experimenter can think of.

Out of the box, the DSP-12 works as a multimode controller, and provides modems for a variety of modes, including advanced satellite operations, in addition to the standard HF and VHF packet and RTTY modes.

DSP-based Filters

NF-60 DSP Notch Filter
JPS Communications
P.O. Box 97757
Raleigh NC 27624
(800) 533-3819, (919) 790-1048
List Price: \$149.95

The NF-60 from JSP is a DSP-based notch filter that automatically

The Down East Microwave

DEM 432K

Continued from page 36

output peaking can be had by adding or removing a turn from L4 and L5. I found in several cases that coils on all boards required at least one-turn modifications either way, but all of these updates are now in the manual.

By connecting your low-level (1 to 3 milliwatt) signal at 28 MHz to the T70, you should be able to measure 40 to 60 milliwatts of energy at 432 MHz with your millivolt/wattmeter. Otherwise, just connect a dummy load or antenna and listen on a 432 MHz receiver for your signal! To verify that the receive converter is working, connect its output to your 28 MHz receiver and use a weak-signal source at 432 MHz. You can also use a handie-talkie several feet away to run this test.

If all has gone smoothly, you've got the basic building blocks of your linear transverter up and running. The next step is to build up the 432PAK amplifier kit. Although you won't need to install the LO/T70/R70 boards in any kind of case yet, you should build the power amplifier right into its chassis before testing it. The PAC-TEC enclosure works perfectly, measuring 4-1/2" long x 2-1/2" wide and 1" deep. Make sure you don't bend the leads more than you have to when soldering the power module to the board.

My approach was to drill and secure the board to the box first, then install the power module (with a bit of silicon grease) to the box with the leads straddling the PC board. (See Photos A & B.) This works very well, offers excellent heatsink capacity and is quite strong. I used 1000 pF feedthroughs to bring bias and operating voltage into the box, while the RF in and out connections are direct-wired with miniature coax.

Once the PA kit is complete, you can test it by applying 13.8 volts to both pins and connecting a wattmeter and dummy load to the output. Connect the T70 board's output to the 432PAK input and apply drive from your 28 MHz source. You should see anything from 12 to 20 watts, depending on drive level. There are no adjustments to make after this.

Packaging

The three boards were designed by Rick Campbell KK7B to be stacked as close as 1/4" from each other. This is a godsend as a space-saving technique, and you can fit all three into the larger PAC-TEC box (8-7/8" long x 5-7/8" wide x 2" deep) with a half-inch to spare. My suggestion is to mount the R70 board on the bottom, followed by the T70 board and then the local oscillator on top. Now you'll want to think about some kind of T/R switching. Although Down East offers their SHF PINK pin-diode switch kit, I decided to use the extra LO pads and a small Radio Shack relay (275-249) to do the trick. Make sure you connect a spike protection diode backwards across the relay—anything will work; I used a 1N4004 as I had a junk box full of them. Photo B shows the detail of the pad up close, as well as a small preamplifier I added to the box. The preamp comes from Steve Kostro N2CEI and uses an Avantek ATF20135 device to develop about 14 dB gain with a noise figure better than 0.5 dB. Photo C shows the finished unit with the cover off. I used chassis-mount SO-239 connectors for the 28 MHz IN/OUT ports, and BNC connectors for receive and transmit connections at 432 MHz. They're spaced to be connected to a Dow-Key DK77 relay, available with 12-volt coils for about \$15 each at flea markets. You can select any spacing you want, and you can also use Tohtsu relays which are sold by Down East to provide a single T/R connection. Simply move the PA compartment down in the box and the relay will just fit on top.

You'll also note the small LED, switch, and RCA connector. The switch is used to go from receive to transmit, and parallels a line to the 5-pin power connector. I can key the unit either from my TS430S, or manually when using a 28MHz radio with no external keying. The LED indicates the transmit mode is active, and 12 volts is sent to the RCA jack in transmit to control a small relay. You could also incorporate a simple RF-shifting TR switch if preferred to hard-wire control.

Performance

I finished the entire kit and all chassis work you see here in two evenings, just in time for the 1992 ARRL UHF Contest. I used an out-board 100 watt solid-state amplifier and a single 21-element yagi to work about 25 stations from Richmond, Virginia, all the way up to New Hampshire. The DEM 432K provided adequate sensitivity, using a Kenwood TS-430S as the 10 meter exciter/receiver. Audio quality reports were excellent, and a small "FMing" problem was quickly fixed when I retweaked the crystal to a more stable position. Actual displayed frequency was within 1 kHz of my true location in the band when the crystal was set to peak output.

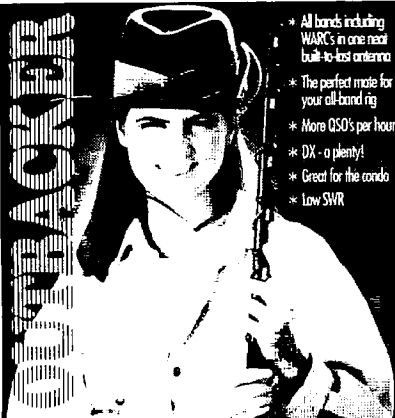

The DEM 432K heard signals (on the average) about 6 dB better than my Yaesu FT-790II transceiver without an external preamp. Plus, I measured greater than 0.15 μ V sensitivity for 10 dB S/N on the bench, using an HP 608F signal generator. More importantly, the DEM 432K shows excellent linearity on the receive side, with a 1 dB compression point (without preamp) in excess of 0 dBm—a lot of signal!

Conclusions

The DEM 432K represents an excellent value for the money. The kit is fairly easy to build if you use care in soldering and keeping track of the chip components. It gives you a complete 70 cm station, using your HF radio as an exciter, and all you'll need is an antenna and some coax to get up and running on SSB, CW, Packet, FM, and satellite operation.

The complete kit of three PC boards and a crystal sells for \$155, while the add-on PA kit without enclosure comes in at \$75, with the enclosure \$135. The 432 MHz preamp kit sells for \$30 without an enclosure, and you won't need the enclosure if it's mounted as shown. Assembled units are also available.

The PAC-TEC enclosures are available through a variety of distributors and retail for about \$18 (#692-900) and \$6 (#351-900). If you visit a few flea markets, you should be able to put a complete unit together for under \$300.

Loose Ends

I don't know about you, but the morning after a party I always find myself shuffling through the house, trying to clean up and put away loose ends. As the new year opens, I feel much the same way about the column this month.

To begin with, a correction. Somehow, the drawing for the VIC-20 I/O connector shown in the November issue of "RTTY Loop" got scrambled. The correct figure is shown here as Figure 1. It is important to note that, according to the information I was sent, there is no "G" or "I" terminal. This makes the pinouts different from the re-drawn illustration in November's magazine.

Next, a "thank you" to the readers of this column for coming to the aid of Charlie Anderson KG5SX. In July I related his tale of woe regarding a fried Hamsoft cartridge. In a letter just received, Charlie tells of several offers to extricate him from his situation, ranging from burning a new EPROM to helping with a whole new unit.

Charlie is now set for digital, and thanks the readers of 73 Magazine and "RTTY Loop" for the help. So do I!

New Problems to Solve

I received a letter from Ralph Brown of Buffalo Grove, Illinois, looking for some guidance in setting up a RTTY receiving station. Not a ham (yet), Ralph has a Panasonic RF-2200 receiver, a HAL ST-5000 terminal unit, and a Model 28 KSR teleprinter, with gear sets for 100, 75, and 60 wpm. In addition, he has an Autek QF-1A SSB/CW/AM filter which, I believe, is an audio band-pass filter.

Well, Ralph, Figure 2 shows you the basic way to hook up your equipment. I have left the Autek filter out of the RTTY circuit, as the ST-5000 has internal filtering sufficient to deal with the audio output of the receiver. To follow the data path, start at the receiver. Audio from the receiver is routed first to the ST-5000, then to the speaker. You can do this in parallel, and a switch to cut off the speaker, so as not to annoy you with the "tweedle-dee," is a fine idea.

The loop supply goes, as you have indicated in your letter, to the loop input of the Model 28. If you have an oscilloscope, connect the horizontal and vertical inputs to the SCOPE Mark and Space connectors, and the ground of both inputs to the SCOPE Gnd connector, to see the common RTTY tuning cross pattern.

Now, with a mark signal tuned in, the machine should be quiet and just

humming along. We can call this idling. With a space signal tuned in, the machine will be making all kinds of noise but printing nothing. This is running open.

Find a signal which sounds like a RTTY signal. This is characterized by a rapid frequency shift between the mark and space frequencies. After you've heard a few of these you'll get to recognize the sound; don't worry. Tune your receiver so that the signal strength is at a maximum on the S-meter, then adjust the beat frequency oscillator (BFO) so that the mark and space frequency pulses are detected by the demodulator.

If all is well, and the signal is Baudot, you should be receiving at this point. You say, "If the signal is Baudot? Say, what?" Well, here's the rub: Most commercial news services to-day regard Baudot encoding as as outmoded as spark. Unfortunately,

How To Get Started In Packet Radio

Enter the exciting world of packet radio today with *How To Get Started In Packet Radio*. Dave Ingram, K4TWJ, wrote this beginner's guide to packet radio in an easy-to-understand manner. It starts with a non-technical description of packet radio, followed by chapters that include getting started, setting up your station, networks, BBSs, portable and high-frequency operation and even a *Packet Radio Equipment Survey*. There's also an appendix that includes circuits for interfacing equipment. **Join the most exciting and rapidly growing area of ham radio today!** Order your copy of *How To Get Started In Packet Radio* book for only \$9.95! (plus \$2.00 S&H).

CIRCLE 223 ON READER SERVICE CARD

the Model 28 teleprinter, upon which your system is based, is essentially locked into Baudot. More modern codes and code systems—ASCII, Sitor, and others—are foreign tongues to your machine. Yes, you can arrange a translation scheme to use the Model 28. Years ago, before the advent of cheap ASCII printers, such schemes were common, with codons such as ".LT." used to represent " ". Whew! Can you imagine a program listing printed that way? No thanks!

So, even if you can get this setup on the air, I am afraid you will be pretty much limited to ham transmissions and the rare commercial station still using five-level code. Several years ago we published a listing of commercial stations still on Baudot; I'm afraid it's hopelessly outdated now. I would be game to hear from any or all of you with information on recently heard Baudot stations.

Speaking of different modes of communication, e-mail received via CompuServe from Michael J. Golbey, M.D., VE7BLD, of Kelowna, British Columbia, addresses his AEA-FAX demodulator. He is wondering if anyone has any experience using the hardware for decoding any other forms of digital communications? For example, it is easy to "see" CW in the monitor mode. It should be possible to write software to display CW, RTTY, etc. Any suggestions would be much appreciated.

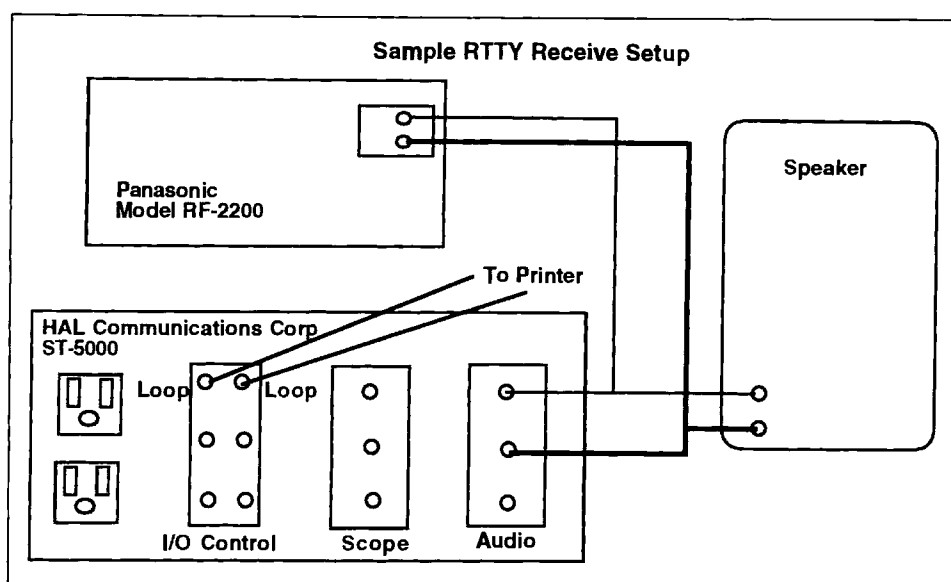

Figure 2. Suggested hookup for a RTTY receive system using a HAL ST-5000 and a Panasonic RF-2200 receiver (rear view connections shown).

Well, Mike, you got me! Let's wait and see what the folks out there say.

Such a way to begin a new year! Overall, I just can't wait to see what the mail brings this month. As always, feel free to drop me a note or e-mail at the above address, or on CompuServe (ppn 75036,2501).

Delphi (username MarcWA3AJR), or America Online (screen name MarcWA3AJR). Of course, the disks remain available, both the "RTTY Loop" Software collection, and the archiving collection detailed last month. Just send disks, either 5 or 3+ inch, high or low density, a stamped disk mailer to return the disks to you,

and \$2 per disk to be filled. Each collection is over one megabyte in size, so be sure to include sufficient media for what you asked for, otherwise I will just pick and choose. Happy New Year everybody. May it be one of health, peace, and well being for each of us, our families, our nations, and the people of the world.

Why buy a TNC?

PC HF FAX + PC SWL \$179.00

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software, instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over shortwave radio. All you need is any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

- Demodulator
- Digital Signal Processing Software
- 200 Page Tutorial Reference Manual
- World wide Utility Frequency List
- Tutorial Audio Cassette with Samples

PC SWL automatically decodes Morse code, RTTY, AMTOR, SITOR, NAVTEX and ASCII. PC SWL lets you tune in on world press services, meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:

- Turning Oscilloscope
- Digital Waveform Presentations
- Auto Calibration and Code Recognition
- Continuously Tunable Filter Frequencies
- Variable Shift
- Adjustable CW Filter Sensitivity
- Unattended Capture and Printing
- Integrated Text Editor
- Integrated Log and Database
- Shell to DOS applications
- Seamless integration with PC HF Facsimile

Call or write for our complete catalog of products. Visa & MasterCard welcome.

ELECTROMAGNETIC FIELD METER

Reduce exposure to potentially harmful electromagnetic fields. AlphaLab's handheld TriField™ Meter measures AC electric fields, AC magnetic fields and radio/microwave power density. Find ground faults, AC current wires or measure high-field generators with the **Magnetic** setting (.2 - 100 milligauss, 60 Hz); identify poorly grounded or shielded equipment, high VDT or fluorescent light fields, distinguish hot vs. ground wires with **Electric** setting (.5 - 100 kV/m, 60 Hz); measure antenna radiation patterns, leaky microwave ovens, etc. on **RF/microwave** setting (50 MHz to 3 GHz, .01 to 1 mW/cm²).

Electric and magnetic settings are omnidirectional, measuring full magnitude of fields without the need to reorient the meter. Price of \$145 includes delivery and one-year warranty.

AlphaLab, 1272 Alameda Ave, Salt Lake City, UT 84102
Call (801) 532-6604 for speedier service or free literature on electromagnetic radiation health risks.

Contact **Bill Ferrell**, (615) 452-3962 after 5 PM M-F, anytime S-S; or write **TVARN**, 1120 Douglas Bd. Rd., Gallatin TN 37066.

LOGic 3's PacketCluster® interface

LOGic 3's PacketCluster interface spots not only unconfirmed DXCC countries but also CQ zones, ITU zones, prefixes, continents, and anything else that can be determined from the call-sign (oblasts, provinces, etc.). Audible CW alert for each award type. LOGic 3's data window is also perfect for RTTY, AMTOR, and CW operation. The flexibility, ease of use, complete logging, awards tracking, and contesting, QSL route facility, and rig control which made LOGic 2 so popular are now enhanced by windowed screens with full mouse support and graphical report layout (MS Windows™ not required). Superb documentation and tech support. LOGic 3 (\$79) and LOGic Jr v3 (\$39) for IBM only. LOGic 2 and Jr v2 still available on Amiga and ST. Soon for Mac. Hard drive required. Free infopak. Visa/mc.

NEVER SAY DIE

Continued from page 67

the body is in danger. This response works on a very fundamental level, operating through what we consider as instincts. Though we quickly become aware of pain on a conscious level, we realize that by that time we've already reacted to it subconsciously. If we had to wait for the pain message to reach the conscious mind and tell us to take our hand off the stove, we'd do a lot of damage. No, the hand jerks off way before we know what hit us.

We learn from this. The next time we see a stove we're suddenly careful and tend not to touch it. This isn't entirely a conscious matter, it's a built-in reaction. Pain equals the vision of the stove on a subconscious level. Well, this is often a very valuable survival system. But like any system that works automatically, it's often going to be wrong and send false alarms.

On a completely subconscious level the mind equates pain with all perceptions being received at the same time . . . visual, sonic, and so on. By the time we have thousands of pain incidents the brain is fairly well tied up with neurons dedicated to these pain avoidance equations. I found this out personally when I worked with people under hypnosis removing these pain equations and discovered that their IQs were measurably zooming upwards and their

mental awareness was going higher and higher.

So what's all this got to do with the prenatal period? Well, the avoidance of pain system seems to be so fundamental that it's in operation right from the beginning. So what pain does a fetus experience? The baby gets all its food directly from the mother through the umbilical cord, right? This means the baby is in tune with the mother. When the mother is in fear her system shoots adrenaline into her blood to help her fight or flee. I hope you won't think it surprising that this chemical attack also shocks the baby. The baby records the sounds being heard and equates them to the adrenaline shock. The sounds are recorded, just as they would be on a tape recorder. The baby doesn't understand what words mean, but in later life that word pattern is going to be equated with a shock to the system and the baby is going to subconsciously react negatively.

Now, the next step in this process. If you think of the baby's mind as acting a good deal like a computer you won't be far off. It's a computer far beyond anything we can even hope to build yet, but it does act like a computer in many ways. The baby gradually learns to deal with its environment. It's very comfortable most of the time during the prenatal period. The temperature is perfect. The food is great. And there's the comfort of a sort of spiritual communi-

cation with the mother.

Babies are programmed very much like computers in that the early instructions are the foundation upon which later instructions are built. If you start with a weak or faulty foundation, no amount of later patches are going to give you the perfection you'd have had without the bad foundation. Make sense? Now do you see why I attach so much importance to what happens during pregnancy?

When mothers don't eat right this permanently affects the child. No amount of good food later on will ever make up for it. When the mother drinks alcohol this zaps right down to the baby. This is traumatic. This is pain! Is it any wonder that the children of mothers who drink during pregnancy have so many problems later on? And the fact is that we're just beginning to find out how many problems this can generate. We know it affects intelligence and health. Well, the same goes for nicotine. When the mother smokes, the nicotine hits the baby like a sledge. Wham! Other stimulants such as caffeine also register as shocks to the fetus. And I don't have to explain how drugs can not just screw up the genetic development of the baby, but set up all sorts of bum basic programming.

There are other shocks which register with the baby such as when the mother falls down or is hit in the stomach. All of these shocks are duly

recorded, right along with the sound patterns for later avoidance.

The birth process is enormously traumatic. Families who are aware of the importance of keeping these pain avoidance equations to a minimum insist on the birth being kept as quiet as possible. No talking. No unnecessary sounds. For years doctors scoffed at this silly notion, but recent research has proven how important a quiet birth can be, so we have fewer skeptics now.

The more we can help women understand the importance to their child of their health, the food they eat, the need to avoid chemical attacks on the baby, and the need for silence when there's a chance the baby might be feeling pain, the better will be the most basic programming of the child.

So how about sex during pregnancy? The baby is going to enjoy this right along with the mother as the pleasure chemicals reach it and the feeling of happiness is shared.

A few people are working on ways of going back under hypnosis and erasing these early pain memories. You can read more about this in *The Holotropic Mind* by Grof (1990—\$20), if you're interested. The first work in this area was described by Alfred Korzibski in his *Science and Sanity* (1935). I plan to write on the nuts and bolts of how to do the repair job when I have the time. But it's a lot easier and cheaper to be careful and not mess up a child's development

(716) 852-3711

during the first nine months, the most basic of all learning periods. I hope this makes sense to you.

Age #2

The second most important educational period is from birth through to about the first birthday. And if you think we're screwing up our children during pregnancy, wait! I'll explain what we've been doing to the little darlings after they're born. You're not going to like this.

Let me ask a very basic question. How important is your child to you? How important is it that your child be given every opportunity to grow up to be the best kind of person you can manage? Would you do anything knowingly that would permanently cripple your child? Would you do anything knowingly which would result in your child having a low IQ? Would you do anything that would tend to have your child become a drug addict? To be an alcoholic? To be a misfit in society? To become a criminal?

What's it worth to you to be fairly sure that your child will grow up to be healthy, intelligent, happy, have a good marriage, and be successful in life? No psychoses? No allergies? If you handle your child's education on every level according to what we know now about how children develop, you'll have a good chance at producing a terrific winner.

Which brings me back to birth, a process which we've managed to louse up almost beyond recognition. So what happens to the kid when you shoot the mother full of drugs so she won't have to feel the pain? Babies need all of the strength they can muster to cope with the birth process. The last thing they need is to be drugged.

Now let's tackle the biggest problem we have with birth, which is what happens immediately after. Think about this for a moment. For thousands of generations children were born and immediately put with their mothers. The child has just spent a few months being fairly close to its mother. It's bad enough to have to get the lungs going and shift to air and breast food, but then to go against a basic instinct by taking the baby away from the mother, it's no wonder babies cry and are traumatized.

We recognize the power of instinct in birds, animals, insects, reptiles and so on. So why are we so blind to human instincts? Do we even for a moment deny they exist? When we look at primitive tribes we find that children are put with their mothers immediately after their birth. Further, they stay with their mothers night and day until they learn to crawl.

The hospital nursery is a cruel, painful time for babies. It goes against hundreds of thousands of years of instinct. When babies are put with their

mothers they don't cry. When they are allowed to stay with their mothers they don't cry.

Allowing babies to stay with their mothers day and night for the first year is going to be even more difficult a change. Our society isn't geared for this. Oh, we're beginning to recognize that mothers should have a few weeks with their babies. We're seeing moves towards maternal leaves from work. We've got to do more than that.

Just the other day I was watching a PBS program showing how young children are treated in various countries. One of the groups visited was a primitive tribe. Here the babies were kept with the mothers. Mothers carried their babies around with them everywhere. The interesting part was that in this situation none of the babies cried. And as they grew up they didn't fight with other children. The kids all happily lent a hand with their younger siblings when needed.

If the whole concept is interesting you'll enjoy reading *The Continuum Concept* by Jean Liedloff (1991—\$9). The subtitle is, "Allowing human nature to work successfully." You'll see why I recommend that businesses encourage mothers to bring their babies with them to work. It'll make happier mothers and babies.

When we separate babies from their mothers we're going against eons of

instinctive behavior. What a great introduction to the outside world! The baby doesn't think, it reacts. It knows something is terribly wrong so it cries. After nine months of being warm and protected by the mother babies need to feel her next to them. They need to feel her warmth, her voice, her touch. They need to feed when they feel hungry.

Perhaps you've noticed that your body tells you in no uncertain terms when it needs food. If you delay the message gets more painful. This is self-preservation at work. Babies feel the same thing, only it's a much more powerful urge for them and traumatic when not fulfilled immediately. Pain! And that means more negative programming of this new computer system. Is it any wonder we're such psychological messes a few years later? Is it any wonder we're all having to diet . . . or at least should?

It's going to take some re-education to change our society so it gives babies the best educational start we can. This means understanding how what we do affects babies during pregnancy. And it means changing things so mothers can keep their children with them for the first few months . . . until they are ready to separate on their own . . . instinctively. Once they're ready they'll start crawling and exploring. Then they'll gradually adjust to being separated from mother and we'll get into Age #3, that time from around the first birthday

CIRCLE 293 ON READER SERVICE CARD

until their formal education starts in school.

This approach should make sense and appeal to most people, despite the need for changes in our society. It fits in with what we know. And if we can bring it off we're going to have far happier, intelligent and better motivated kids.

There are some less obvious influences on babies that we'll eventually have to deal with. We can see some of these at work with other animals. You've seen the way schools of fish can change direction instantly. We've seen how people can change when they are in a group. We need to understand more about how mob psychology works. What turns individuals into a lynch mob? Into a cheering political group? Into mass-hypnotized rock 'n' roll groups? Into feeling a group religious experience?

And how do we deal with mental communications which occur on a subconscious level and are thus extremely elusive to study? If I'm encouraged to explain how to repair the mind . . . how to find these pain avoidance memories and erase them . . . then we're going to get deeper into the metaphysical. Then we're going to start dealing with life, death, past lives, reincarnation, and other things that are outside our normal Newtonian, Aristotelian everyday world.

It's a lot simpler to accept the obvi-

ous. The sun comes up every day, so obviously the sun is rotating around the earth. Do you know that there is a fair percentage of Americans who don't understand that the earth circles the sun? When we look at matter we know it's there. We can see it and feel it. Then we go to school and find out that matter is made up of molecules. Molecules are made up of atoms. And atoms are made up of electrical charges all held in place by forces which we don't see, feel or experience in everyday life. Newtonian physics doesn't hold when you get outside of our normal frame of reference. Nor does Aristotelian logic.

Quantum mechanics doesn't make any Newtonian sense at all. We're changing electrons into photons and back. We're splitting photons and suddenly we're defying time. Well, this is where we're getting in our understanding of how the brain-mind-spirit-body work. A book you'll find absolutely fascinating is *The Holographic Universe* by Michael Talbot (1991—\$10). But get a good grip on yourself because you're in for a wild ride . . . and you'll never be the same again.

As you begin to understand how the mind and body are integrated you'll see where I'm headed when I suggest we investigate how the mind works as a better approach to health care than just treating germs, viruses, and other symptoms. I suspect that for about the same investment it takes to bring one

new drug to the market we could prevent around 90% of sickness via tackling the psychological components which have triggered the problems.

When I get some time I'll continue on with my recommendations on Age #3, which will include the day-care and pre-school years. It's during this critical period that around 80-90% of our life patterns and habits are established. It's a lot easier to teach good survival patterns during this period if we start with a solid foundation of learning from conception on through the break with mother . . . into when we can use language for communication.

Babies and Hamming

What has all this got to do with amateur radio? Why should you care one zot about how babies are brought up? Well, I'm trying to solve a problem and, as in most solutions to problems, it's necessary to go back to some basic roots. My aim is to help improve our American quality of life. That's my most basic goal. It's obvious to me that the more skilled our work force in the next century, the better off we'll be. We see low-skilled jobs being moved to lower wage countries and we know that this is a process that can't be stopped. We can fight it with rhetoric and tariffs, but marketplace competition will eventually win out. You can't keep imports out with tariffs. Look at the hundreds of billions we're spending trying to keep out drugs. And look at

the total failure we've had with this approach.

Okay, we need higher skilled workers. This means skills in high-tech businesses and manufacturing. And this means better education and motivation. So I envision our having millions of kids interested in amateur radio as a way to be motivated to learn. We know from our history that if we get kids interested in hamming early on they almost invariably continue on to be technicians, engineers and scientists. In the '50s an ARRL study showed that 80% of all hams who started in their teens went on to high-tech careers.

So my approach is to provide the educational system which will attract youngsters to high-tech hobbies such as amateur radio, computers, electronic experimenting, and so on. And, the more I looked into the educational system, the more I understood how it starts out at conception, not when kids first enter school. So there you are.

We need to make major changes in our Age #3 educational approach. And we also need to make even greater changes in our Age #4 system, which takes us into adolescence. Hey, we'll get all this into shape eventually . . . and when we do, we'll not only be a model for the whole world (again), we'll be the leaders in an incredible world market for our educational products. And that's going to be a trillion-dollar market.

Techno Whizzy, Part II

Continued from page 14

OK, but more than 0.3 volts means something is wrong. Check the biasing resistors—and is the transistor in backwards? (Mine was.)

Hook the RG174 cable from RF out on the DDS VFO board to the input (J3). Plug a scope into the "hot" end of R5 and apply power to the TW-1 via the J2 on the power supply board. If you're still set to 7040 kHz and channel 12, you should see a nice sine wave at about 0.7 volts peak-to-peak. Hook the scope up to the output at C3 (you should see very little), then key the unit and you should see 4 volts p-p. That's 40 milliwatts, enough power to make a contact by itself. However, we can run a little more than that, so let's do the final amp.

Hook the scope up to the center conductor of the antenna jack and key the unit. You should see a nice sine wave at over 15 volts p-p. Turn switch SW1 off and it will go away. If you don't see this, check the usual suspects—resistors of the wrong value, transistor dead or in backwards, mis-attached transformers, etc.

This amplifier is linear down to about 11 volts, but below that it has a small amount of distortion. To remove this distortion will require a filter between the amp and the antenna. I've included a schematic for a five-pole

filter that'll keep your TW-1 FCC legal if you run with a low battery, and a parts list indicating what values of caps and inductors to use. Boards for this are available from FAR Circuits (18N640 Field Court, Dundee IL 60118), and a chart of what components to use for different bands is listed in the sidebar.

If you want to run the TW-1 on all bands with a dying battery, you'll need to switch in different filters. Use a two-pole six-throw switch (available from Radio Shack) to switch different filters in and out.

You're done with the "radio" part now, so let's do the case. Pick a nice case—you'll want to show this off at the club. Make sure there's some extra room inside for a few more boards (for the digital front-panel and receiver boards, at least).

The back of the TW-1 needs a power jack, a fuse, an antenna jack and a reset switch. I usually use an SO-239 or RCA phono jack for the antenna connector, and a panel-mounted fuse holder (so I can change the fuse without dismantling the radio). The power connector needs to handle about 1.5 amps. The reset switch is an SPST NO momentary push-button switch—you'll probably never need it but it's there just in case.

On the front you'll need room for a 12-position rotary switch, the T/R switch, the key jack and perhaps a light to remind you the TW-1 is turned on. Label each position

of the switch for which frequency you're using. The key jack can be a 1/4" headphone jack—run your TW-1 from a straight key or a keyer.

Congratulations, you've just done the impossible—built your own home-brewed digital radio! Prepare to have fun with your new Direct Digital Synthesized Techno Whizzy model 1 transmitter. Maybe you'll be the first DXCC with QRP DDS!?

So, what's the next step? How about a digital front-panel with LEDs and a keypad for frequency input to replace the diode array? Or a receiver board to turn the TW-1 into a full transceiver? Or a mod to use the TW-1 as a signal generator with tracking, to turn your oscilloscope into a filter sweeper? Or a mixer to run the TW-1 at 6 meters? How about adding 8K worth of battery-backed-up memories and a CAT (computer assisted transceiver) interface? SSB, anybody? Maybe a 5-watt amplifier stage?

All of these are planned, and the first two are being prototyped already. Watch for them in the next few months. If you have an idea you'd like to add, drop me a line. I can explain what's planned for the 50-pin headers so your device won't interfere with the other boards.

You can write to me at 1307 N. Richmond Rd, Apt H, McHenry IL 60050, or contact me on Usenet at jjw@precipice.chi.il.us or on CompuServe at 70410,1642.

Notes from FN42

It is now the beginning of a new year. What lies before us? Might it be world peace? It is encouraging to hear that some countries that have been having civil wars are now pursuing peaceful means of settling their differences, as in Mozambique as reported by Phil Gray KA7TWC/C9RPG.

We as hams have a chance to exercise our rights to help each other and to help new hams get started in our wonderful hobby. Last year I mentioned that a group of hams in the Keene, New Hampshire, area had provided evening classes for the Novice/Tech licenses. I just finished talking to several of those who participated in the teaching of the classes and they have all enthusiastically volunteered again, even the one who spent many hours coordinating the effort. All we need to do now is set the place and the dates and let the word be known to the local media, packet, local nets, etc.

If you feel that you can't do this, or that you will let someone else do it: Before you make that final decision, please read the parable in the news from Australia. Then, think about how it relates to amateur radio and you.

GET INVOLVED! 73, Amie N1BAC.

Roundup

China China Ham News, Issue No. 1 from the Tsinghua University Amateur Radio Club, edited by Rick Hunter, Public Relations Manager: Hello from Beijing! BY1QH is the radio shack located on the 4th floor of a dorm on the campus of Tsinghua University. The campus is located in the northwestern part of Beijing, roughly 10 km from the city center, Tiananmen Square.

The equipment in the shack consists of an ICOM IC-750A, an AEA PK-232 TNC, an IBM 286 computer with a 20 meg. hard drive and monochrome monitor, and a four-element 14 MHz yagi, a three-element 21 MHz yagi, and a vertical. We have an ICOM amplifier that is inoperable at the present due to a bad 2SC2652 (we think). That sort of part is very difficult to locate here so if anyone might have one laying around and would send it to us, we would be extremely grateful.

We were honored to have Mr. William Santelmann N1AU from Massachusetts pay a visit, along with his friend Carl Lehr, on April 10, 1992. Besides having a look around the radio shack, Bill gave a terrific lecture on "The Incredible Ham Radio" to as many as 200 Tsinghua University students. His talk was very warmly wel-

comed. Bill also kindly presented us with the 1992 ARRL Radio Amateur Handbook and a copy of "CT," well-known computer software for contesting logging developed by K1EA.

Mr. Bob Boyd W1VXV from Maine, together with his XYL Carol, had an eyeball QSO with us on September 2, 1992. Unfortunately, we had some problems with our rigs at that time so he couldn't operate, but they had a good time talking with the students on campus. The Boyds previously visited BY1BJ and BY1PK.

BV3AC of Tsinghua University in Taiwan, and BY1QH of Tsinghua University in Beijing took part in the Jamboree-On-The-Air (JOTA) activity in October on 15 and 20 meters. JOTA is an annual event sponsored by the World Scouts Bureau in Geneva. Our special gratitude to Mr. Wang Wenlong BV3AC for his wonderful ideas and information.

BY1QH has just registered at the JASTX AMTOR/PACTOR mailbox. Because of our limited output power and the recent poor propagation, this might be the only mailbox that is available to us. Feel free to pass messages to us at JASTX.JPN.AS. [The path works because I have already passed a message and received a reply passed back by VE7CIZ—Amie]

We are quite new to packet radio, although the interface we are using may enable us to show up in the BBS mode. We badly need to know how to get into a BBS and any information will be appreciated. Is e-Mail available from a BBS?

Our present QSL information listed in the callbook is PO Box 2654, Beijing, People's Republic of China. If you have sent a QSL before but have yet to receive one in return, we would like to mail another, provided you request again. A BT80TUA Special Event QSL (voided) will be sent simultaneously as a gift. For faster reply use the address at the end of this file.

The latest figures show that there are 77 amateur radio stations all throughout China at present. BY1QH has the QSL Info on 76 of them, which might be of help to you. Don't hesitate to ask if you have no idea where to send the card. An SASE is of course nice to have.

Our thanks go to Bill N1AU, Bob W1VXV, Wang BV3AV, Ted W2FG, Ray NV2A, Don W8OJQ, Jim N2HOS, Joe N4QQ, Wang BY1BJ, and Tong BY1PK for their support and help. In addition, special thanks to JA1AN for sending us JARL News magazine, and to our Taiwanese friends who have mailed us their CO Amateur Radio magazine. In particular, thanks to JASTX for making all this news file possibly known to others.

For further information, or any help that is available, please send messages to me at JASTX.JPN.AS, or at this address: Rick Hunter, Room 316, Building No. 25, Tsinghua University, Beijing 100084, People's Republic of China.

The BY1QH news may be sent by any means to anyone or any institution without asking for permission. Our sincere appreciation to you for letting others catch up on our news.

[This information was downloaded from packet. It was downloaded from JASTX at VE7KIT on PACTOR, then distributed by VE7CIZ, George. VE7KIT is in contact with JASTX (Mitsou's PACTOR/AMTOR BBS in Kochi) two or three times a day. If you have messages that you would like to send to BY1QH, you can send them to VE7CIZ @ VE7KIT. #VANC.BC.CAN.NA, and he will be glad to pass them on via JASTX.—Amie]

Philippines Sent by Rainier R. Baulista DY9CKQ CQ, CQ, CQ . . . OUR RADIO CLUB IS DYING! The world of amateur radio is expanding in some parts of this planet Earth. Every second, the airwaves are so crowded with so many languages, sharing ideas, jokes, hobbies, experiences and so many other things a human being would like to express. Somewhere, there are hams going on DXpeditions while others are hunting for more and more fellow hams in the air for their DX awards. Others are learning the Morse code and reviewing their theory of simple electronics and radio laws while others are assembling and testing their home-brew radios or perhaps constructing their magnificent and gigantic steel towers decorated with different kinds of antennas . . . yet somewhere in this world, an amateur radio club is dying.

It was 1985 when the Organization of South Cotabato Amateur Radio (OSCAR) was organized in the southernmost part of DU-land, the Philippines. It actually started here in our town, Koronadal or Marbel, but the members were outnumbered by their invited interested parties from Gen. Santos City, which is 57 kilometers away. When the association was registered with the Securities and Exchange Commission, it was addressed to them and they got most of the credit from the Philippine Amateur Radio Association (PARA) and from everywhere else in the world as DX9-OSCAR. During those times, the group constructed a repeater station at the foot of Mt. Matutum, but it was not strong enough for a hand-held transceiver to trigger. For more than a year now the repeater station has not functioned due to some technical problems.

There is one president of our club, while there are two people for the rest of the positions, i.e., two vice-presidents, one for the city and one in South Cotabato; likewise for the secretary, treasurer, auditor, and press relations officer. The group has one

organizational chart, but on functional aspects it is separated. Here in Koronadal, the station is called OSCAR-MARBEL.

In 1990 I began to have an interest in this hobby so I joined OSCAR-MARBEL because one of the organizers was my father and he had suggested the name of the group. He was not able to continue this expensive hobby because of the examinations. I was an associate member, being the second operator of Dr. Gerte Pingoy DU9EP. Now I have my own callsign, DY9CKQ, as a Class "D." I have just passed the 5 wpm CW and I will be upgraded to DU9CKQ as Class "C" in December. This means I could already operate on HF and my dream of DXing will be realized somewhere in the future.

At my age (21 years old, second youngest member of the group) and as a graduating student in a Norte Dame school, I was nominated and elected this month as 1993's vice president of OSCAR-MARBEL. I "won" because I was the only nominee. Nobody else would dare to handle the responsibility of leading a dying organization. That is why I had to take the role because I saw and felt the importance of amateur radio in our community.

During the first four years of OSCAR-MARBEL's existence the group was very active when it came to communication, fellowship and sportfest, community service (monitoring the peace and order of the town for 24 hours), and they could even garner 40 to 60 stations to check in during the net. In the fifth year, the achievement of the club started to deteriorate and it even ceased its operation twice, for almost eight months between 1989-1990, and for three months in early 1992. Today we can have five to 15 stations join our net even though there are 50-75 hams within the town, not to mention associate members.

Perhaps leading the club at this age is somewhat difficult, but I think it is a good experience and opportunity for me to undertake. Yes, of course, I have my own dream—a dream of having a conversation with a lot of people out there—a dream of having certificates and plaques displayed on the bamboo walls of my small room—a dream of becoming a hamwriter, sharing my experiences and ideas that could contribute to the development and progress of radio amateurism and that could inspire newcomers—a dream which made me move forward and have a deeper interest in this hobby. Yes, I know that it will be a long, long way to go, and I believe that along the way, helping to reactivate my club, my dreams will be achieved.

And the question goes again . . . is our radio club dying? If I have to base my answer on the present situation, "No, it is not. It's just being paralyzed!" But if I have to compare it to the past activity of the club and to the

status of other amateur radio organizations, "YES, OUR RADIO CLUB IS DYING!"

For all of these, I am just wondering if there is anybody out there who could extend their help to the development of our amateur radio club here in the southernmost part of the Philippines? If so, please write to me at the following address: Rainier R. Bautista DY9CKQ, OSCAR-MARBEL, c/o Marbel Peterpan, Koronadal, 9506 South Cotabato, Philippines. [Does this sound like your club or a club you know? If you can help, do so. It means so much for so many people, especially Rainier.—Amie]

Republic of Slovenia Letter from Joseph Zelte W8FAZ. Source: Slovenec, October 22, 1992: Anton Stipanich, President of the Association of Radio Amateurs of the newly formed Republic of Slovenia called a press conference on October 21. The occasion was the coming worldwide competitions involving some 3.5 million amateurs in 300 countries.

"With the attainment of self-government and independence of the Republic of Slovenia, the Association of Radio Amateurs of Slovenia has likewise arrived where its members will be able to take an active part on the world scene. For on October 24 they will get the new call signs whose first part, S5, indicates the Republic of Slovenia." [The information received and published last month was incorrect; 4N3 may be for Croatia.—Amie]

It was the Slovenian amateurs who first let the world know what was going on during the brief failed June war last year. In the Bosnia war, Slovenian amateurs have been contacting fellow hams there and getting all kinds of information. Thus the thousands of war refugees in Slovenia are learning about the true situation regarding their relatives back home.

The association is comprised of 89 clubs, including over 300 active members. In the tradition of amateur radio, President Stipanich further pointed out that Slovenian amateurs especially stand out during natural catastrophes and disasters. For example, during the heavy floods last spring hams provided many reports. Beside their contribution in the Slovenian war effort, they also aided the victims of earthquakes in the areas near Slovenia.

Stipanich also saw the worldwide competitions scheduled for October 24 as an excellent opportunity to promote Slovenia throughout the world.

Frank Mocnik KP4AOD of Orlando, Florida, reports that S5 would signify Slovenia. A second numeral would indicate the district. Thus S51, S52, S53, etc. will probably be the new international prefixes replacing the old defunct Yugoslav YU3 call sign.

Switzerland From the International Telecommunication Union Press: The Asia Telecom 93 Exhibition and Forum will be held in Singapore from 17 to 22 May 1993 under the theme "Telecommunity; The Next Era Of

Growth." Hosted by Singapore Telecom and the Telecommunication Authority of Singapore, Asia Telecom '93 is organized by the International Telecommunication Union (ITU) and will take place in Singapore's World Trade Centre, ideally located and offering advanced exhibition and forum facilities.

For additional information, please contact: Ms. Suzan Hee-Sook Lee, Project Manager, Asia Telecom 93, International Telecommunication Union, Place des Nations, CH-1211 Geneva 20, Switzerland. Tel: +41 22 730 5811; Fax: +41 22 740 1013.

USA Note from Stu Stephens K8SJ: "I will be active as VP2MK8SJ, Montserrat, British West Indies, February 5-17, 1993: all bands, mostly CW, 20-30 kHz up from the low-band edges. QSL via the 1992-93 Callbook address: Stu Stephens K8SJ, PO Box 266, Girard OH 44420. Non-SASE QSLs will be routed through the Bureau. All QSOs will receive a QSL!"

AUSTRALIA

David Horsfall VK2KFU
PO Box 257
Wahroonga NSW 2076
Australia

I have been waiting for further details of the new licence structure in Australia, and by the time you read this, they will have announced it at the SEANET '92 Convention in Darwin, Australia. The announcement itself would have been relayed on the various WIA broadcasts. Apart from the general deregulation of conditions (especially packet radio), Novices are expected to be the main beneficiaries. My next "73 International" column will carry full details.

The VK4 (Queensland) Division of the WIA and the Queensland Department of Education have submitted a joint proposal to the DoTc on using ATV to link classrooms during school hours, when most amateurs are at their jobs. Comments from amateurs were solicited, and this has already upset a few people, who appear to be concerned about the "commercial use of amateur bands." This is an ideal opportunity to expose school children to amateur radio, but naturally it will need to be carefully controlled to ensure that amateur frequencies remain in amateur hands.

A recent High Court decision has upheld the right to "political" free speech, to counter a proposed ban on political advertising. It is worth noting that Australia has no right of "free speech" as such. The relevance to amateur radio is its possible impact on the packet radio network, since sysops (system operators) were free to delete what they thought were obnoxious or illegal bulletins; this is now thought to be in doubt by some.

Finally, it appears to be fashionable amongst the uninformed to "bag" the WIA (Wireless Institute of Australia) for various perceived shortcomings,

and I gather Australia is not alone in this respect. Whilst no organization can be 100% perfect, amateurs' interests would be better served by offering constructive criticism and volunteering to help wherever necessary. I leave you with this parable, relayed to me by Richard Murnane VK2SKY, although it may not be original: A man was wandering alone in the mountains, in the middle of winter, and in great danger of freezing to death. Just as darkness was falling he came across the smoldering remains of a tree that had been hit by lightning. He said to the remains of the fire, "I will get you some wood and build you up into a fire, but only if you warm me up first," and lay down next to it. The next morning, the fire was dead. By some odd coincidence, so was the man...

Cheers for now. Those with access to Internet or packet can contact me as "dave@esi.COM.AU" (note the new address) and "VK2KFU @ VK2RWI.NSW.AUS.OC" respectively.

MOZAMBIQUE

Phil Gray KA7TWQ/C9RPG
c/o CARE, C.P. 4657
Maputo
Mozambique

Peace at last! Or at least there's a good start. Through the efforts of several western and southern African nations, Mozambican peace talks began in Rome last year. The peace initiative in Angola was also helpful in getting the discussions started. After several months of false starts and more months of various derailments or disappointments, peace was finally signed 3 October 1992. This was good news and a very important first step, but there was no dancing in the streets. The ordinary Mozambican has had so many promises broken and hopes dashed in the past 15 years that he has become a very wary, if not cynical, person. When I arrived here in January 1987, the country was Marxist, destitute, and in the middle of a civil war in its 12th year. But worse, amateur broadcasting was prohibited!! Even so, four

hams have been granted limited broadcast permits over the years: an employee of the Swedish Embassy, a German tourist, and the traveling Colvins. But the efforts of the rest of us finally paid off last year when the government legalized amateur radio and opened an official radio club in May 1991. Since then we have been on the air in fits and starts with an American, Steve Marshall C9RSM, the most frequent user. There may be a total of seven of us, two of whom have stations at home. After I installed the SatellLife ground station at the university medical school in December 1991, I was on OSCAR 14 until February when amateurs were moved to OSCAR 22.

The urban economic situation began to improve as Russia underwent its changes three years ago, but conditions in the rural regions remained the same—or worsened—as the war continued.

So what now? Elections are to be held within 12 months and I have seen campaign posters up already—a positive sign. The countryside needs to be rid of marauders, thugs, and gangs that prey on villagers and farmers. This will take perhaps five years alone, maybe 10. The roads and railways need to be rehabilitated so goods and people can move within the country and exports/imports can cross its borders. South Africa and Swaziland are 50 miles away from the capital, Maputo, but we cannot go due to bandit or rebel attacks. We look forward to a safe drive before I leave in June—just to say we've done it.

With a coastline the length of California's, there also is (and was) tourism capability. That, too, needs to be rebuilt and staff trained. And speaking of training, most of the schools in the country have been severely damaged and books lost, stolen, or destroyed. Same or worse for the hospitals.

So we're at a critical point in the nation's history and development, but at least and at last amateur radio is back on the air. Listen for us on the weekends.

MMIC Amplifiers

This month I will cover MMIC amplifiers. A few questions have popped up from our readers covering surplus MMICs and how to identify them. I will focus on surplus MMICs that I have obtained, describing how to identify them. There is no problem in component identification for those who purchase exactly what they desire, but what about those of us who scrounge components and MMICs from surplus PC boards? How do you recognize and identify them?

I will also cover the pinout information for the most popular MMIC amplifiers. This can be confusing—in my own scrounging I recognized that a different series of markings was used to identify each component but I didn't realize just how far this marking scheme went. Identification of devices from several manufacturers or even between devices from the same manufacturer on surplus PC boards was, at the beginning, not easy. The further I explored this the easier it became, and I am sure it will be easy for you as well.

What I got into in my trip through the junkyard surplus dealers were component parts labeled A-06, A-01 (letter-number), and 414 (totally numerical). Other devices had dots of various colors on top of the plastic case of what I believed to be MMICs. These were the devices that partially populated the surplus PC boards of interest to me. The problem with these miniature components and corresponding miniature part numbers is one of identification. You must realize that this numbering scheme is not limited to just MMIC amplifiers but can cover transistors, GaAsFETs and other devices. Some of these packages can have very small case dimensions with correspondingly small identification markings because there's not much room for large part numbers.

For instance, GaAsFETs seem to be identified with a two-letter code like Af, Be, Hj, etc. I have not yet broken this code for the GaAsFETs, but I believe these devices are manufactured by Fujitsu. Better luck prevailed with the MMIC amplifiers—I was able to decode their part numbers.

The MMIC amplifiers that I obtained on the PC boards were quite easy to decode once I figured out that the manufacturers were Avantek and Mini-Circuits Labs. Determining the manufacturer of the devices helped considerably in identifying their components, giving away further clues on how their component parts were labeled. The main problem lies in the fact that these are miniature components and cannot

contain a full part number. They have just a partial number and this must be used to recognize them. This isn't tough but it can be intimidating until you recognize the format. To become familiar with these part numbers you must browse through parts manuals in your field of interest to pick up subtle facts and store them in your memory for recall.

Avantek Parts

First, let's discuss a little about device package styles. Devices are available in a variety of case styles from leadless chips to high quality ceramic to low cost plastic packages. This case style in some instances takes into account the physical dimensions of the package, like the MSA-0685: The MSA-06 specifies the type of device; the "85" calls out a 0.085-inch plastic package. The various Avantek part numbers all have this simple format in common—the last two digits represent the case style. Until I understood this I was trying to keep a larger part number straight in my head and I was not having much luck trying to figure out that an MSA-0385 and an MSA-0386 were not too different at all, just case styles. I guess I got stuck on the old 2NXXXX and 1NXXX numbering schemes. Once I got this straight, it cleared up a lot in the MMIC amplifiers for me. See Table 1 for other package types.

There are still a few quirks in the labeling of devices but let's cover them one at a time. Avantek devices, both transistors and FETs, have a similar base part number. Transistors begin with the prefix "AT" and FETs begin with "ATF." Only the three-digit number following each is different. The last two digits reflect case style. In the case of MMIC amplifiers, the part number begins with MSA and has a four-digit part number. The first two identify the part

while the last two identify the case.

MMIC amplifiers can be supplied from the two different major suppliers, Avantek and Mini-Circuits Labs, but be careful—they are identical in specifications but differ in device orientation. The Avantek part is keyed on the output of the device with a dot or triangle imprinted or a dot depressed in the case, denoting output. The device number, such as "A-06," is also imprinted on the top.

The Mini-Circuits MMIC

The Mini-Circuits MMIC is printed with a color-coded dot on the input, opposite the Avantek orientation. Don't ask me why but that's the way it is. I suppose that Mini-Circuits wanted to differentiate the MMIC amplifier they sell from Avantek's. Just be careful to note which device you are working with. They do use different marking indicators so it's easy to tell them apart.

Surplus MMICs

What started all this was some surplus printed circuit boards that our group picked up. From the first, I thought all the devices on the PC board were MMIC amplifiers. However, once I consolidated the component markings with some common sense and a few catalogs, the identification process came together. Some of the devices I was able to scrounge off of these PC boards were the MSA-01, -02, -03 and -06 devices, all MMICs. The transistors were part number AT-414 and AT-420 devices.

The -01 devices are rated to 1,000 MHz while the -02 and -03 devices are rated to 2,000 MHz. Power gain runs from the 13 to 18 dB gain at 100 MHz to 12 dB at 1,000 MHz and 10 dB gain at 2,000 MHz. The noise figure runs in the 5 to 7 dB range with the -01 device having the 5 dB noise figure. The maximum power output for these devices runs from 0 dBm for the -01, to +3 dBm for the -02, and +8 dBm for the -03 device.

Figure 1. Noise head construction: transistor AT-42085 or any NPN device with high f_t . Set R1 for 1-2 mA current through the Q1 base emitter.

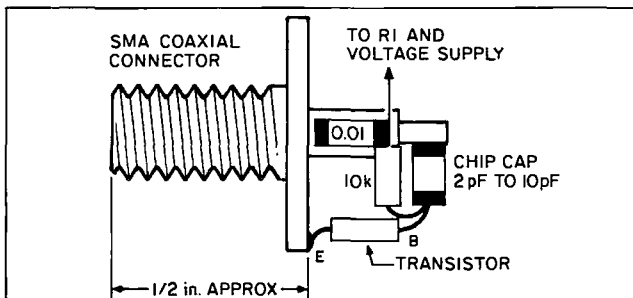

Figure 2. Parts placement method. For best high frequency noise operation, use a chip capacitor to couple the SMA pin, using the shortest possible lead lengths from the capacitor to the base and emitter to the ground.

Figure 3. Possible alternative to the circuit shown in Figure 1 (see text).

I was pleasantly surprised to find that the -06 device (actually an MSA-0685) has 20 dB gain at 100 MHz and 11 dB gain at 2,000 MHz. The noise figure is 2.8 dB. Not bad for a broadband device, even with the output power limited to zero dBm. You just can't have high power and a low noise figure at the same time, with low cost. In any case, this -06 device should be quite good for general purpose amplifiers in low noise applications. Even at a 2.8 dB noise figure this should be quite suitable for many older radios serving as a broadband preamplifier. See my column in the April 1992 issue of 73 for other MMIC specifications for Mini-Circuit MMIC devices.

The A-414 and A-420 devices scrounged from the PC boards are bipolar transistors good to 6 GHz. The 414 device (AT-414) has a noise figure of 1.7 dB at 2 GHz and a device gain of 13 dB at 2 GHz. The 420 device (AT-420) is a little more husky, giving +20 dBm output power (that's 100 mW), a gain of 13 dB, and a noise figure of 1.9 dB, all at 2 GHz. Quite a device, especially from the junk box. One surprise is that I use the Avante AT-42086 transistor normally and don't know why I did not recognize it at first. My devices came in a tape reel and were upside down—that must have prevented me from associating them because of their orientation in the tape reel (at least that's the excuse I am using).

RF Noise Source/Generator

These 420 devices have been the mainstay for pet microwave projects in my shack for some time. I have used them for so many different projects and applications even I can't keep track of all of them. The most interesting and simple application that I used them for was a noise generator. This unit works from a low frequency of a few MHz up into the GHz range. The circuitry is quite simple and only requires a current-limiting resistor and chip capacitor for coupling. Only two leads of the transistor are used—the base emitter junction. The collector is left open.

The principle is that with forward current flowing through a junction, noise will be generated up to the "Frequency Total," or Ft, of the device. Since these devices are rated to 6 GHz they worked quite well into the several GHz range. This little project can be used to drive MMIC amplifiers to increase the power output. Why, you say? Well, noise generators can drive bandpass circuits with sufficient power and the output can be observed being indicative of its frequency response. This shaped noise can be displayed on a spectrum analyzer depicting bandpass vs. frequency. (A sweeper is not needed.) The noise generator and MMICs can complement one another.

The power supply is the only complicated thing in this entire project. It can be as simple as a 9-volt battery and regulator which will provide noise output whenever it is switched (turned on). A more complicated unit would be

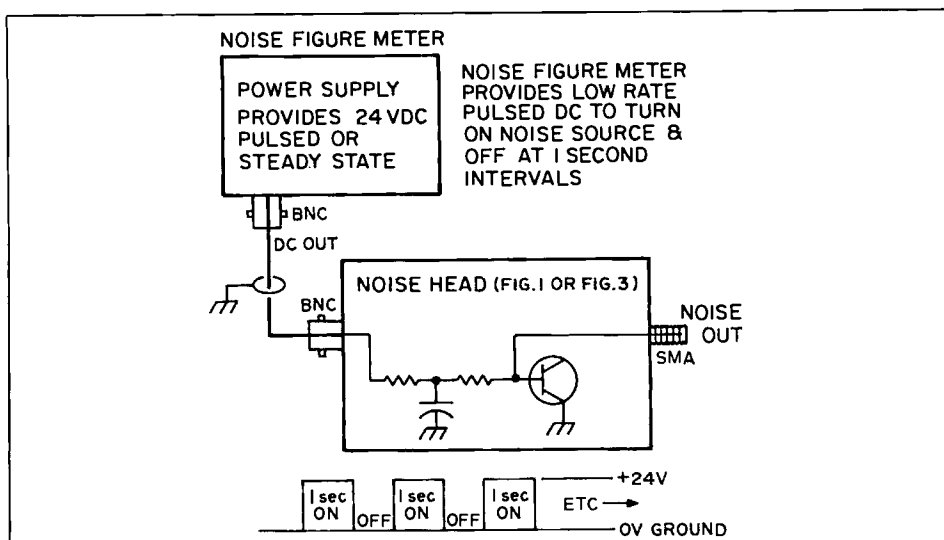

Figure 4. Noise head operation. If DC power is steady, noise output will be continuous. If DC power is pulsed, noise output will be pulsed. A pulsed noise source is useful to determine the difference between noise to no noise for the noise figure ratio.

composed of a power supply/battery that could be pulsed on and off at a set rate. This pulsing power supply is what really makes the noise source perform and is the most common method of operation. A noise figure test set normally provides all power supply functions for the noise head, as well as displaying the measured noise figure directly in dB. The test set additionally has circuitry to do all the computations to give you a display or readout of the actual noise figure.

A simple noise source similar to the one described this month for steady-state noise will work just as well without all the calibration accuracies of a conventional full-scale noise figure meter. All you have to do is read the difference in output of your receiver (noise source on and then off) and determine from the ratio of noise-to-noise just what your noise figure is. It's not complicated to figure out your noise figure, but you need not go through the math. With a noise source instead of a signal generator, tune your system for best noise performance and you're done. True, you don't know exactly how well it's working but it will perform better than if you tune it up with a signal generator.

In actual practice, it's easy to peak up your system's performance by using such a simple noise generator. Just adjust your preamp and RF stages in a receiver for maximum noise as detected on the output of your receiver. Don't start from scratch to do noise alignment this way—as stated before, your receiver must be operational first. The noise alignment method is used to peak or maximize the best performance, not to do a total alignment of a radio. See Figure 1 for the construction details of a simple AT-42086 noise generator RF head. It should be constructed with minimum lead length as the longer the lead length the lower the maximum frequency of operation will be.

To minimize lead length I chose to construct the noise generator on the

back of a miniature coaxial connector, an SMA type chassis connector. This connector is made to work with coaxial cable (solid shield 0.141-inch diameter) that is quite small in diameter. It is intended primarily for microwave operation and is good to 18 GHz. In our application, small is better as this helps to keep lead length to a minimum. This improved high frequency operation (in the GHz).

In normal operation a special noise diode is employed to do the function of generating noise. In our application we are replacing the diode with a base-emitter junction of a microwave transistor as they work quite well and cost a lot less. The circuit for the noise generator is quite simple and uses few parts. See Figure 2 for the component configuration to minimize on lead length. The basic circuit uses four parts: a coaxial connector, a chip capacitor, a chip resistor and the microwave transistor. To use the circuit, provide a source of DC power positive to the base of the transistor through a current-limiting resistor set to draw about 1 mA of current to start with. This resistor value will vary depending on your transistor. Normally, you should start with a high value resistance, say 50k ohms, and adjust lower until you read 1 mA of current. Maximum current should be no higher than a few milliamperes. I use a 24-volt power supply with two 10k resistors in series with my transistor and draw 2

milliamperes of current. The second 10k resistor originally was a pot for best adjustment but it works well with the fixed resistor for miniature size.

Figure 3 shows a modified circuit for better high frequency response. I haven't experimented with this circuit yet but it might be interesting to try. It is supposed to provide higher frequency noise output than Figure 2 by lifting the diode anode end (our emitter) from ground and terminating it in 50 ohms. The RF output is directly fed from this point. I prefer the first circuit (Figure 2) for DC isolation and simplicity reasons. The transistor used in either circuit is the Avante AT-42085, which has a frequency rating good to 6 GHz. If you can't locate a device, I will provide a kit of parts including several Avante transistors and the resistors and a chip capacitor. You will have to come up with your own coaxial connector. By the way, the SMA connector is not the only one that can be used; even a type "N" is suitable—it's larger but works quite well. Cost of the parts kit is \$7 post-paid. (Note that any microwave npn device will work in this circuit; it's the high frequency junction, base to emitter, that gets the job done here).

Well, that's it for this month. next month I plan to cover packaged mixers in general. As always I will be glad to answer questions concerning this and similar topics. Please include an SASE for a prompt response. 73 Chuck WB6IGP.

00	Chip only	Bare chip only

Table 1. Package types and case styles (last two digits only) of Avante devices.

**(Update on last month's Update . . .
the saga continues.)**

Baby Loopy

Refer to the above article on page 34 of the October 1992 issue. The formula that reads

$$\frac{19 \text{ turns } (3.14)^2}{12 \text{ inches/ft}} = 9.94 \text{ feet}$$
 should read as

$\frac{19 \text{ turns (3.14) } 2}{12 \text{ inches/ft.}} = 9.94 \text{ feet.}$ The value of 2 is the coil diameter in inches.

A 2 Meter FET Amplifier for Your Handheld

Refer to the above article on page 20 of the October 1992 issue. The schematic diagram and the parts list shows the value for R5C1 and R5C2

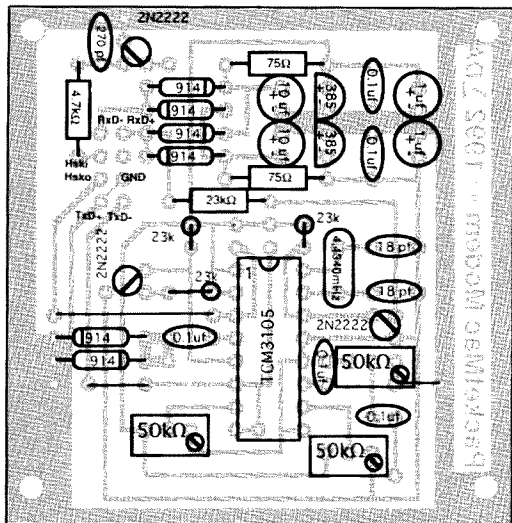

Figure 1. The corrected (and hopefully final) parts placement diagram of the Pack-
etMac Modem showing the jumper wires as well as the new pad assignments
(shown in red). Using these new pad assignments, just follow the wiring hookup
chart in Figure 4 in the original article for the proper connections.

Figure 2. Updated parts placement diagram for "A 2 Meter FET Amplifier for Your HT." The MRF 137 transistor is configured in such a way that it will not fit readily on the PC board shown in the article. There are two ways to fix this. One is to bend the transistor leads and squeeze them through the mounting hole. A better approach is to cut away openings in the board at 45 degrees to the source and gate and at 45 degrees to the other source and drain as shown here. 1/4" wide by 3/8" long cutaways probably will be sufficient. Also note that if a chip cap is used for C5 on the board, a lead will have to be run from the cap to the foil in order to make a connection to the diodes.

reversed. RFC1 should be 20 turns of #16 wire, 0.3 inch diameter. RFC2 should be a 100 μ H choke.

The following changes to improve the amplifier's performance have been sent in by the author: The diodes on the output (D5 and D6) get hot; putting two other diodes in parallel with D5 and D6 will solve this problem and increase the power output. Communications Concepts, inc. is a source of many of the parts for this amplifier. You can reach them at 508 Millstone Dr., Xenia, OH 45385; Tel: (513) 426-8600. For C1 and C12, use an ARCO 406; For C2 and C4, use an ARCO 403 and 404 respectively. C3 calls for a 56 pF Unelco capacitor and C5 uses a 680 pF chip cap. Adding C13 (0.01 uF chip capacitor) in parallel with C8 appears

to improve the amplifier's performance. RFC2 can be replaced with a Ferroxcube VK-200-10/4B choke.

If you still cannot get the rated power out of the amplifier, try putting a 144 MHz signal into it. Adjust the trimmer capacitors and R3 for maximum output and record it. Then send a 148 MHz signal into the amplifier and repeat the procedure. If you get more power out at 148 MHz, then the amplifier is resonant above the 2 meter band. Try replacing L1 and L3 (or both) with coils that are a quarter-turn longer than the original ones. Keep experimenting until maximum power is obtained. Conversely, if you have more power output on 144 MHz, then you should shorten one of more of the above coils.

**IT'S A SNAP WITH THE ELEGANTLY SIMPLE
MORSE TUTOR ADVANCED EDITION FOR
BEGINNERS TO EXPERTS—AND BEYOND**

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops).

TABLE OF CONTENTS

February 1993

Issue #389

FEATURES

- 10 Fun at 10,000 MHz
Explore the wide open spaces of the 10 GHz microwave band.....WB6NOA
- 16 The 23-Foot Indoor Antenna
Make an effective 20 and 80 meter apartment-dweller antenna.....G2BZQ
- 18 Accurate Low Cost VSWR Meter
Convert this CB accessory for 1.8-450 MHz operation.AD5X
- 20 An Effective 160 Meter Antenna
How to build one on a small residential lot.KA6MMQ
- 26 The "Simplest Transverter"
Check out the 6 meter band with this inexpensive 2 meter interface...W3RW
- 30 Build the Tone Processor
Eliminate interfering signals with this versatile switched capacitor audio filter.....JA1AYO

REVIEWS

- 34 The Down East Microwave WSSK
Microwave weak signal source kits.....KT2B
- 42 The GAP Voyager DX-IV Vertical
Operate 160 through 20 meters with this high performance antenna...AG8L

FEEDBACK... FEEDBACK!

It's like being there—right here in our offices! How? Just take advantage of our FEEDBACK card on page 17. You'll notice a feedback number at the beginning of each article and column. We'd like you to rate what you read so that we can print what types of things you like best. And then we will draw one Feedback card each month for a free subscription to 73.

Learning Code Even Faster

The no-code license has doubled our newcomers, but this is only pulling off the misery. You still have to learn the code to get in on most of the fun amateur radio has to offer. So why not at least make the process as painless and as fast as possible?

My advice is to go for 20 wpm right off the bat. The weird fact is that it isn't any more difficult to learn the code at 20 wpm as it is at 5 wpm, so why multiply your aggravation? I sure wish I'd known about this when I was learning the code! Alas, I used the ARRL system, which was right out of the Dark Ages and provided a maximum of misery and a minimum of success. The upside, as far as many hams are concerned, is that this system alone was responsible for discouraging millions of potential hams from getting licenses.

We know a lot more about how the brain-mind-body system learns skills now than we did 50 years ago. Not that all this scientific data has perked through to most of the code learning systems, which are still firmly rooted in the 1920s. Now we're having people able to learn the code at 20 wpm within a few days—a skill that often used to take years.

Recent research at the Weizmann Institute of Science in Israel has shown that your best time for learning a skill such as copying code is to do it shortly before going to sleep at night. You do your practicing, and then you sleep on it. This lets the brain-mind-body integrate the skill faster. Experiments where people were awakened during the REM part of their sleep—while they were dreaming—slowed down the learning curve substantially. So go to sleep and dream.

How long should you practice? As long as it's fun. I'd recommend 20-minute sessions. As soon as it stops being fun and exciting, don't push it. Remember, you're building a new skill, one that will be with you for the rest of your life—one that will set you apart from people without that skill. You're learning a new language.

In case you've missed my explanation of how to go about learning the code, or have been too cheap to buy my 20 wpm practice tape, which comes with the instructions, here's the process. It's simple. Instead of learning the dit-dahs

of each letter and number and starting out at 5 wpm and gradually speeding up, you jump right in at 20 wpm and start listening for one single character—like an E. Even at 50 wpm you can hear the dit as an E goes by. Every time you hear that dit you write down an E. It won't take long for this to become fairly automatic. Once it's easy, you start listening for did-dits and writing down I's as well as E's, and gradually work your way through the alphabet, numbers and punctuation.

The old system, where you learn all the characters first and then look them up in your mind when you hear a sound pattern, keeps your brain busy shuffling between the two halves of your brain—one which recognizes the sound pattern and the other with that look-up table of characters. This works pretty well until you get to about 10 wpm when you've reached the clock speed of the brain, if I may use the computer analogy. That's the famed plateau, hanging in there just under 13 wpm. So near, yet so far. Unfortunately, no amount of sweat and strain can change this. You just have to start all over and learn the code the way you should have in the first place—weeks or months ago. Years in some cases.

What you're going to do is build a new motor skill, like typing or playing the piano. Only this time it's you writing or typing code characters as they zip by. You hear the sound, your fingers move. Good high speed ops can copy code in their heads while talking with someone, it's so automatic.

I'd recommend you get my 20 wpm practice tape, but I'm sure some crummy nit-pickers would complain that I'm going commercial. Mine is inexpensive, it's a fiendishly-planned class-A bitch to copy, and it'll do the job. You sure aren't going to memorize this baby.

We're ABC!

Oh whee and big deal. Well, it's a big deal for 73, now that we've had our circulation audited and our sworn claims verified by the Audit Bureau of Circulation. Rough talk to deal with. But frankly, I got tired of what I've believed to be total baloney sworn circulation claims by some ham magazines I could mention. As it turns out, ABC certified our 1991 circulation at several thousand more than we reported ourselves.

In almost any other industry advertisers and their agencies understand that unless a magazine's circulation has been audited and certified, there's little chance that the sworn claims are even in the same ballpark as reality. You have to remember that advertising is normally charged on the basis of so many dollars per thousand paid readers, so the more the publication lies, the more money they make. And money does odd things to people.

It's all the worse when one magazine claims double or even triple its actual paid circulation, while another plays it straight. Honestly just isn't the best policy when your competitor is lying and his lies can put you out of business. That's where ABC comes in for most industries. They make a magazine prove every claimed paid reader. Their accountants come in and go over every record with a fine-toothed comb. But the end result for advertisers is the knowledge that the certified circulation is really true.

About the only reason for a publication not to be certified these days is that a close look at their figures would prove them false, so reputable advertising agencies tend to avoid doing business with them.

In the amateur radio field, 73 is the only magazine which has been certified by ABC.

I remember the first time I discovered how wild the circulation exaggerations could be in this field. I was the editor of CQ at the time. My assistant editor slipped into the CQ offices one night and made a copy of the actual circulation figures and brought it to my house. I was astounded. The actual paid circulation was less than half what I'd been told and what the notarized sworn statements claimed. We were charging over double what we should have for our ads.

The next day I found out that after giving me the figures my assistant editor had gone to the publisher and told him I had the actual circulation figures. He expected, correctly, that I'd get fired and he'd be the new editor. The publisher assumed I'd taken records, so the next morning he demanded I return them. He drove me to my house, picked them up, and fired me. He was terrified that he might be sent to prison for falsely sworn statements.

I was surprised, but not dismayed, at being fired. CQ was raking it in, turning

a profit of well over a million dollars a year in today's dollarettes . . . mainly because of the bogus circulation claims . . . and I was getting bupkis. Oh, I'd been promised that if I pulled the magazine out of the red I'd share in the profits. Well, I did. For Christmas that year I got a \$5 bonus, and then I was fired a few days later. That was my share of the profits.

The magazine had been stiffing the authors. They were at least a year behind on paying every author I checked on, and over a year and a half on most columnists. I had to pay for articles out of my pocket in order to get them. When I was fired they owed me over \$10,000 in 1960 dollars . . . around \$100,000 today. The publisher promised to repay the loans. I'm still waiting.

That circulation scam worked so well for the publisher that after I'd been fired he sent out sworn statements for about three times the actual paid circulation . . . and advertisers were stupidly paying up.

After getting fired I tried working for an advertising agency. I found this really wasn't what I wanted to do. My hobby was amateur radio, so what better to do than publish a ham magazine? That was *fun*, so I started 73, even though I only had just barely enough money to print the first issue. It was one heck of a gamble. CQ was telling the industry not to advertise in 73 because it would soon fail. Fortunately, not all advertisers believed them, so I made it.

I started out doing everything. I solicited manuscripts, edited them, took the photos, sold the advertising, went to hamfests to sell subscriptions, got the magazine into over 850 ham stores with the help of Jim Morrisett WA6EUX (now K6MH), wrapped 850 bundles of magazines every month and mailed them, cut stencils for new subscribers, printed thousands of magazine wrappers for the subscriber copies, sent out the invoices for advertising and store copies, made the bank deposits, kept the books, and so on. It was a lot of work, but I made it go, despite everything CQ was doing to stop me.

In addition to all that I was the president of the Porsche Club, organizing car rallies, helped found American Mensa, helped organize the ARRL New York convention, and was doing my best to cope with a sick wife. 1960 was a busy year. Heck, I was almost as busy then as I am now, over 30 years later.

It'll be interesting to see if 73 being audited by ABC will encourage the other ham magazines to get their circulation figures certified . . . or if advertisers, seeing that they may have been paying for phantom circulation, start demanding audits.

Audited magazines that don't provide the promised paid circulation have to refund advertisers for the shortage. Of course I have no way of knowing for sure if any of the other ham rags are shortchanging the advertisers, or by how much; but when advertisers in 73 tell me their identical ads in another magazine are selling only half as much of their

LETTERS

Number 2 on your Feedback card

From the Hamshack

Richard Ashley NS1ZC, Salt Lake City UT Just yesterday I was driving south on Interstate 15 about 35 miles south of Salt Lake City when I had to pull off the highway because of a minor mechanical problem. Within a few minutes a Utah Highway Patrol car pulled in behind me and offered assistance. However, he also took note that my vehicle was registered in Texas and I was not from here. I'm only a temporary resident. After determining my problem the patrolman took close note of my ICOM IC-02AT handheld, my Yaesu HF rig and my ICOM 2 meter mobile rig. The mere appearance of these radios in my vehicle really agitated the patrolman and he literally demanded to know why I had three "scanner radios" in my vehicle! I explained what the radios were and that I was an amateur operator. He flatly refused to believe that and, to top it off, he was going to confiscate my equipment unless I could provide my original license! I explained to him that my "original" was framed on my wall back home in Texas and offered him a copy. That was not sufficient. He believed that anyone with "sophisticated" radio gear was a dope runner or involved in some sort of criminal activity, and made no qualms about being quite vocal about it. I have never been accosted like this by any law enforcement officer, and it was only after I spent over an hour sitting in his cruiser being checked out that I was allowed to finish my Thanksgiving Day journey.

It seems to me that the amateur community should make the law enforcement community more aware of mobile amateur activities and the help they can provide. I may further add that I have made a written report to the officer's superiors here in Salt Lake City. I would be curious to know if this is just an isolated incident, or has this or anything similar happened to other amateurs?

Arnold Samuels, Ocean Shores WA Wayne, as I read your "Never Say Die" column religiously, I see you always refer to the amateur radio service as a "hobby." As a hobby, I see no reason why the U.S. taxpayer should support us; as a service, it should. I never see the FCC refer to us as a hobby—why do you? It is high time you change your attitude and start calling this hobby a service, which it rightfully is.

Arnold—You'll find that I am pretty careful about the words I use. Amateur radio is a "service" only because of the hobby it provides. The sorry fact is that very few hams are willing to spend much of their time providing service. Somewhere around 99.9% are rag-chewing, working DX, contesting, mangling useless traffic, jamming nets, certificate hunting, and kerchunking repeaters. Some service.

Of course, as you say, the FCC refers to amateur radio as a service. This is an enormous lie and most of the people at the FCC know it. What we have, in fact, is a government-

sponsored entertainment medium mainly of interest to middle-class older white American males and to Japanese youngsters, which allows a very select few of us to use tens of billions of dollars in public frequencies.

On rare (and getting rarer) occasions we're able to provide emergency communications, but with the popularity of cellular phones, our help is being needed less and less. We've contributed pathetically little in technical developments in the last 30 years. We no longer can supply technically skilled operators for the military in time of war as we did during WWII, when 80% of the hams joined the services. Of course, that was before the hobby went geriatric.

Service? Oh sure. Cheers . . . Wayne

Carlos M. Herrera N2OIZ, North Bayshore NY I just received my subscription-ending December issue—subscription-ending because I thought I wouldn't be able to afford to renew due to my current financial condition. So I read your editorial, which is always the first thing I read in 73. Well, I'll be signing on again and I think I have a simple solution to increase both subscriptions and readership.

I am not only going to renew, but one of my ham friends will be getting a gift subscription this Christmas. Now, if every subscriber you currently have does the same for one of their friends or relations you'd see a definite increase in readership, ergo more interest by the big advertisers. If your current subscribers can't bring themselves to think of a worthy soul maybe they can give a gift subscription to their local library (which probably can't afford it) or to a ham club in a local school. There might even be a tax benefit (for the real skintails!)

Last point: You're right (again). With all the interest in ham radio there's got to be some way to make a decent living at it. I intend to find it (or them). Wayne, thanks for the inspiring words: Never Say Die!

Bill Roork VE3MBF, Agincourt, Ontario, Canada Wayne, I look forward each month to reading your editorials. As far as I am concerned, you make more sense than the rest of the ham magazines put together.

I particularly want to congratulate you for mentioning the book about electromagnetic fields (November 1992). After reading just part of that book, I am convinced there is a serious problem, one which we no doubt will be hearing about a lot more.

As a member of the Scarborough Amateur Radio Club, I am the educational coordinator. We offer "Code and Theory" classes each year as part of our effort to help save amateur radio. We use a system which is unique in our area. Instead of having one person teach all the lessons, we use a different Instructor each week. All instructors are members of the club and donate their services without remuneration.

We find that because each instructor appears only once, they go to great lengths to prepare their lecture and, most importantly, they bring in many, many exhibits (resistors, capacitors, diodes, lubes, transistors, coax, transformers, etc.) to illustrate the subject of the evening.

We have two public events per year where we promote amateur radio. One is at a large local shopping mall in the spring. We have a table display, exhibits and signs, plus a working rig to show. We encourage those interested to join our "Code and Theory" class which starts in September. We get quite a few prospects.

Our other major effort is one day (usually a Sunday) at the Canadian National Exhibition in Toronto. This occurs in August, and there is an amateur radio station (VE3CNE) where a local amateur radio dealer loans a number of transceivers, keys, paddles, tuners and computers to demonstrate packet radio. The antenna system at the VE3CNE station is the property of the station, funded by contributions of metro area ARCs. Since all the metro area clubs participate in the CNE program, amateur radio in the area gets quite good exposure (several million people per year) and we all get cards signed by interested people of all ages.

Over the last four years, our club has had in excess of 160 people join and go through our class. The pass rate has been very high, with many people getting an amateur radio license.

So far as the "Code and Theory" classes are concerned, there is one problem. That is, that while the code is still a requirement for full licensing, it is becoming increasingly difficult to purchase straight keys and code practice oscillators at a reasonable cost. The best we have been able to do is to show the students how to make a very inexpensive code practice oscillator using the following: a straight key, a wood block, a 9-volt battery, a piezo-electric buzzer (Radio Shack or other) and two feet of wire for connecting. Thus, for about \$12, one can build a quite usable code practice oscillator, provided a straight key at a reasonable price (say, \$7) can be found.

In view of the fact that the licensing structure requires Morse code at 12 wpm to gain access to all amateur radio frequencies, we really stress that all students should learn the code. We furnish a cassette tape with computer-generated code at 6, 8, 10 and 12 wpm as a starter. As you have often pointed out, it seems ludicrous that we require people to learn an obsolete discipline like CW so they can be fully licensed—while at the same time the licensing structure almost ignores the important DIGITAL technology, where future development appears to be heading.

You have proved repeatedly that you are a clear thinker with many constructive and innovative ideas. As one old geezer to another, I take my hat off to you for your comments on education, effective government, entrepreneurial opportunities and many other subjects. I hope you will be able to publish your common sense ideas for a long time. As a former Olympic and pro ice hockey official, minor hockey coach, engineer, multi-plant

manager and consulting engineer, I find that you are one of my very favorite people.

John Beegan, Streamwood IL I started in radio as a Cub Scout and built a crystal radio with the help of an older student. I still remember how fascinated I was to hear real radio coming out of the headphones. And no battery or wires plugged into the wall socket!

Later, I built a Meisner kit radio which had several tuning coils for various bands. I kept this radio through high school and left it to the science department of the school. Building and soldering and making connections, reaming holes in an aluminum chassis, inserting grommets—it was all fun.

One time I was building a radio that required a battery for power. I made all the connections and checked them. The radio would not work. I asked my dad and he said to re-check everything. I did; it still did not work. Finally, I went to the next-door neighbor, Mr. Miller, who was a bus driver. Mr. Miller looked at my breadboard, looked at the schematics, and said, "This damn thing will never work, the way they got it." He then advised where a connection had to be made (or where a connection was called for that should not have been indicated), and of course, then it worked. Mr. Miller had studied radio and TV repair, and did a "moonlight business" out of his basement, fixing TVs for the neighbors.

It was from Mr. Miller that I learned that the book is not always right. Sometimes the experts know more than the guy who wrote the book. That's why I am writing you. I am a police officer, and the "official" version is: "Radar won't hurt you." I picked up 73 and read your review (November 1992) of *WARNING: The Electricity Around You May Be Hazardous to Your Health* by Ellen Sugarman. As you so correctly pointed out, electrical fields can have an effect on living tissue. That's why they use X-rays for treatment of certain medical conditions.

At present, every American is exposed to high-tension wires, and to scatter radiation from TVs, radios, microwave ovens, electric blankets and police radar. Virtually every motorist in almost every metropolitan community is being dosed with radiation from radar guns. All of this in the name of the law, of course. And to add insult to injury, the citizens themselves are taxed in order to pay for the radar that is then used on them. Additionally, there have been several court cases where police officers have alleged that they have suffered serious effects from the use of the police radar—serious effects like cancer.

Of course, there is an alternative. Laser guns that measure traffic speed have been produced and are already on the market. The drawback is cost. The laser guns cost more than the radar units. It also appears that the laser guns are much less likely to be abused or misused than radar guns because they are more precise.

Don't let up. Keep putting out a strong signal, and let the world know. Most people will eventually take the message to the polls. Politicians who do not listen need to be replaced. It's happened before, and it will happen again.

Canadian Amateur Radio Organizations to Merge

Executives of Canada's two amateur radio organizations met in Cobourg, Ontario, on October 3, 1992, to iron out the details of their merger. The new organization, to be known as Radio Amateurs of Canada, is comprised of the members of the Canadian Radio Relay League and the Canadian Amateur Radio Federation. In addition to reviewing the complex legal issues involved in such a merger, the delegates from CRRL and CARF also affirmed maintaining a Canadian national field organization, established a committee to study the national Capital Region headquarters office, reviewed a proposed Radio Amateurs of Canada operating budget, and affirmed that all former CRRL and CARF members will continue as RAC members with all services. *Via ARRL Letter. TNX Westlink Report #638, November 27, 1992.*

Cosmonauts to Fly on the US Space Shuttle

Cosmonauts Sergei Krikalev U5MIR and Vladimir Titov have been selected to fly on the US Space Shuttle next year. Both cosmonauts will be arriving in Houston shortly to begin their training. At this time, it appears that Titov will be trained as a back-up in the event Sergei cannot fly on this mission. There has been no word whether U5MIR will operate SAREX amateur radio equipment from the Shuttle as he has from the Russian space station *Mir* in the past. *TNX KD2BD; W5YI Report, Vol. 14, Issue #20, October 1, 1992.*

Earthwinds Setback

The Earthwinds attempt to circumnavigate the world nonstop in a manned capsule suspended between two special balloons suffered a setback just days before a scheduled liftoff. During a media tour of the launchsite near Reno, Nevada, a 29 mph wind gust ripped a hole in the top of the large inflatable dome that served as a hangar for the project. The dome quickly deflated, exposing the 100-foot-diameter anchor balloon (already inflated in preparation for liftoff) to the high winds. The anchor balloon broke free from its moorings and rolled nearly a quarter mile across the desert floor until it deflated after suffering damage from the sagebrush. Fortunately, no one was hurt and the gondola only experienced minor damage. The top balloon was still in its packing

crate and was undamaged.

The anchor balloon will have to be either repaired or replaced. In addition, a new hangar dome will have to be installed. It is expected that repairs should be completed in time for a possible launch in early January 1993. This still gives the Earthwinds crew a two-month launch window.

During this historic flight look for the ham radio tracking experiment on 28.303 MHz. At 30 and 55 minutes past each hour there will be a transmission giving the balloon's latitude, longitude and ground speed during the flight. The callsign will be KB7JGM. *TNX to Bill Armstrong and Erin Porter of the Earthwinds Hilton project for the above information.*

Ban on Cellular Scanners Signed

President George Bush has signed into law legislation that blocks the sale of radio equipment used to eavesdrop on cellular telephone calls. It directs the FCC to withhold its equipment authorization for any radio scanner that can receive cellular frequencies or that can easily be modified to receive such frequencies. The equipment cannot be sold without FCC authorization.

In about a year the law will also make it illegal to manufacture this type of equipment in the United States or import any such equipment made elsewhere. *TNX N7EP; Westlink Report, Number 639, December 10, 1992.*

Hams Aid in the Wake of Killer Tornadoes

Ham radio operators from throughout the South have rallied forces to aid victims of a series of devastating tornadoes that ripped through Mississippi, Tennessee and Alabama on Saturday night, November 21, 1992, and Sunday morning, November 22nd. At least 16 people were killed, with countless others injured and homeless.

All but one of the fatalities occurred in Mississippi Saturday night. At least six died when a tornado hit a trailer park in Brandon. The other reported death occurred in Toone, Tennessee.

The storm knocked out power to many homes in Rankin County, Mississippi, near Jackson. Also disrupted were many normal lines of communications, including telephone and cellular telephone service. At least one 2 meter repeater was damaged and knocked off the air, but most others

survived unscathed and were pressed into immediate relief operations service.

With the traditional communications services taken out, hams accompanied rescue workers who used doors from ripped-apart trailers as makeshift stretchers to move away the injured, according to a civil defense official.

In western Alabama, Danny Buford KC4RLR spent the following day in Ethelsville, which was also hit by a severe twister. Buford used his amateur radio gear to help assess damage for the Red Cross. According to KC4RLR, he saw at least three homes that were destroyed and many house trailers damaged beyond repair. Buford said that it was all but a miracle that nobody was killed in Ethelsville, where seven people were hospitalized.

Amateurs involved in "Skywarn" severe weather spotting nets stayed on the job overnight. They were reported to have seen a tornado touch down about 11 p.m. and reported it and other critical storm information to authorities via 2 meter FM. The National Weather Service confirmed the sightings on Sunday the 22nd, noting that this help may have kept the death toll from growing higher. *Westlink Report's* Youth Editor Sam Garrett AAØCR and 1992 *Westlink Report* Young Ham of the Year Angie Fischer KBØHXY were written up in the St. Louis, Missouri, newspapers for their participation in Skywarn operations.

Earlier Saturday, tornadoes caused serious damage and several injuries in parts of southeastern Texas. Skywarn hams also reported that a tornado touched down in southern Iowa as well, causing several minor injuries. And in Ohio, members of the Dayton Amateur Radio Association took the DARA Emergency van to a suburb of that city after a twister touched down, causing minor damage on Monday November 23rd. *TNX KB4KCH, N8FPF, NØDN and others; Westlink Report, Number 639, December 10, 1992.*

Fun at 10,000 MHz

Explore the wide open spaces of the 10 GHz microwave band.

by Gordon West WB6NOA

The 10 GHz band has plenty of elbow room for activity—would you believe 500 MHz wide? And on any warm weekend you can usually find plenty of activity on 10 GHz if you take a little drive to the local hill or a mountaintop.

There are two companies that manufacture 10 GHz systems: Advanced Receiver Research Company (wideband FM transceivers), P. O. Box 1242, Burlington CT 06013, (203) 582-9409; and SSB Electronic USA (narrowband SSB/CW transverters), 124 Cherrywood Drive, Mountaintop PA 18707, (717) 868-5643.

For local contacts out to 100 miles line of sight, wideband FM works great at 10 GHz. The Advanced Receiver Research transceiver is completely assembled and is ready to go for voice, MCW, video, or data. You could run up to 100 mW output with a M/A-COM Gunnplexer, part of the \$500 TR-10GA transceiver system. Just add 12 volts and a simple Radio Shack mike and you are on the air, full duplex, into a little plastic horn antenna that points in the direction of the other microwave station. For just about a grand you could get on the air INSTANTLY with the two ARR transceiver systems. On a hot summer afternoon you could probably exceed 100 miles of communications range due to the atmospheric condition called tropospheric ducting. The higher you go in frequency, the more pronounced the tropospheric duct gets, and the further you can communicate. My best range with the ARR system was 245 miles from Southern California down into Baja California.

Avid microwavers have not been content to work only out to a couple of hundred miles. They wanted a 300- to 400-mile range, so they switched from wideband FM over to SSB, and as soon as a few SSB 10 GHz systems were on the air, contacts were achieved well beyond 300 miles.

Photo A. The ARR 10 GHz FM system makes an ideal mobile microwave station.

The SSB Electronic USA Station

Fortunately there is a way to easily build a portable SSB or CW station for the 10 GHz band using the modules and components available from SSB Electronic USA.

A typical station would consist of the following:

- XLO-1 local oscillator module
- XTM-1 10.368 GHz transmit upconverter
- XRM-1 10.368 GHz receive downconverter
- HP-8761 single-pole, double-throw, SMA RF switch (or equivalent)
- SMA to 10 GHz waveguide adapter
- Control relay
- Output TR relay
- Multimode 2 meter transceiver

The XLO-1 local oscillator module puts 5 mW on 2556 MHz. A fifth overtone crystal at 106.5 MHz is used in the temperature-compensated oscillator circuit, and all multiplier stages are filter-coupled in order to achieve a clean output.

The XTM-1 transmit mixer requires a LO injection signal of approximately 5 mW at 10.224 GHz. We set the on-board attenuator

Photo B. A completely portable 10 GHz SSB station (200 mW output) can be easily assembled through the use of the SSB Electronic USA 10 GHz transverter, a 2m multimode rig and a horn (or dish) antenna.

Photo C. A horn antenna is a good choice for portable 10 GHz operation. It can be easily fed with a waveguide-to-N-connector section. Standard coax adaptors reduce the feedpoint to an SMA connector.

Photo D. The 10 GHz horn antenna is easily bolted to the waveguide flange.

to approximately 100 mW of IF drive from a modified Kenwood, Yaesu or ICOM 2m SSB transceiver. (The transceiver needs to be modified to cut out the PA section in order to limit power output to no more than 100 mW.)

An active GaAsFET mixer is utilized to provide a sum and difference output of 10.224 GHz, plus or minus 144 MHz IF input. The summed output of the mixer is selected by an on-board cavity filter tuned to 10.368 GHz. The resulting signal is amplified to approximately 200 mW output by a three-cavity coupled GaAsFET amplifier stage. That's right, folks, a whopping 200 mW output!

The XRM-1 receive module contains a mixer for an injection signal of approximately 5 mW at 2556 MHz. A separate SMA connector is provided for low output at 10.224 GHz for transmit mixer operation. Received signals are amplified by a two-stage, low-noise GaAsFET preamp with a noise figure of about 2. A cavity filter follows the preamp to provide filtering. A mixer is used to provide IF output at 144 MHz, going to your multimode transceiver.

Assembly

I chose the Kenwood 751 multimode transceiver because it was easy to cut out the PA section for an almost perfect 100 mW output. My thanks to Craig Martin at Kenwood for the documentation to insure no output spikes. On the back of the Kenwood 751 is a jack connected to an internal PTT relay, and this allows me to control the 10 GHz transverter for a simple push-to-talk operation. You must make absolutely sure you don't lose your PTT circuit to the transverter—transmitting while the transverter is still on receive would mean immediate destruction of the receive module.

RF switching is accomplished with an expensive HP SMA 12-volt RF relay. You can find plenty of 28-volt relays at the swap meet, and this is an alternate way to go if you can't locate a 12-volt relay with SMA connectors. You will then need to convert from the SMA jack over to an N-connector, or directly to the 10 GHz wave guide that will match up with your 10 GHz horn or dish. I run a horn and also have an optional

two-foot and four-foot dish from Anixter Mark.

The modules are completely pre-tested and pre-assembled inside their rectangular silver cans. Jerry at SSB Electronic USA relies on the hams to do their own setup of the individual modules. Jerry indicates it's a weekend job, and most of the time will be spent in "plumbing" all of the components together to match his suggested layout.

The total component cost for my entire system, INCLUDING THE 2 METER MULTIMODE TRANSCEIVER, was a little over \$1,000—exactly twice the amount of a pre-assembled wideband FM transceiver. There was also several days time spent in putting everything together, testing, tuning, and tracking down some of those illusive RF relays.

Performance

Once the system gets turned on and warmed up, stability is rock-solid. I tuned into several 10 GHz CW beacons, and after warm-up there was no noticeable drift. The beacons are an excellent way to double-

Photo E. Close-up of the "plumbing" to the SMA 12-volt relay.

Photo F. Jim Ford N6JF measured over 210 mW output on 10 GHz using the SSB Electronic USA transverter (shown on the lower left of the workbench).

check that your receive system is up and running properly.

For transmit, output at 205 mW was confirmed with some elaborate waveguide tap-off equipment, but was confirmed using a simple microwave leak detector available from Radio Shack. Holding the microwave leak detector near the dish or horn aperture revealed plenty of energy coming out of the system. While the little Radio Shack microwave oven leak detector is not very scientific, it was the best thing going during the recent microwave contest when no one else up on the mountaintop had any real way of knowing that their system was up to par.

Our first contact was with Bill Alber WA6CAX over a path of 305 miles between Southern California and Arizona. He assembled his own SSB Electronic USA system, but opted for manual switching between TX and RX. We both used Anixter Mark two-foot dishes, and we had signal strength to spare.

We found that we could bounce the 10 GHz SSB signals off of passing aircraft, too. After all, 10 GHz is where most marine radars work. It was interesting to hear the Doppler shift as the aircraft was approaching both our stations.

So if you're looking for new frontiers to explore, and want plenty of elbow room, do consider the 10 GHz band. On any warm weekend there may be as many as 20 or 30 operators in your area participating in some mountaintop activity. Use a separate 2 meter transceiver for coordinating your contacts, or switch over to a relatively small horn, point in the general direction of suspected activity, and tune around looking for a signal. You might be surprised at what you hear!

Presently Southern California ham radio operators have their sights on setting a new 10 GHz SSB record between California and Hawaii, with Paul Lieb KH6HME up and

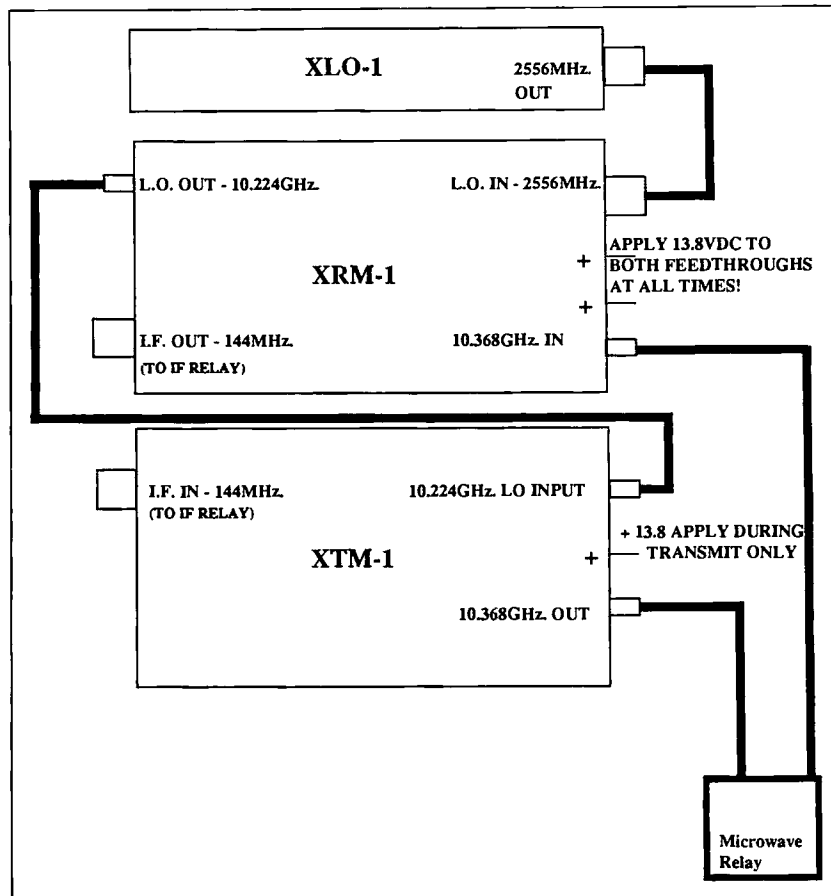

Figure 1. 10 GHz transverter interconnect diagram. Courtesy of SSB Electronic USA.

running with 10 GHz equipment. While 10 GHz "experts" say it can't be done at the 200 mW level, time will tell! The right conditions could open up a 10,000 MHz path

like no one has ever suspected before.

Come on up to 10 GHz—there's plenty of elbow room, and there's no shortage of pre-assembled equipment.

Build a Super-Horn Antenna for 10 GHz

With the concept that bigger antennas have more gain, I thought it would be fun to develop and build a 10 GHz horn antenna with a lot of gain . . . one that would just fit into my station wagon for mobile microwave use.

From the 10 GHz antenna bible, the *RSGB VHF/UHF Manual*, I found a passage which described a horn antenna as a "Waveguide feed appropriate to the frequency (WR-90 waveguide) which is smoothly flared in both planes so that a wave inside the guide horn can expand in an orderly manne . . ." In other words, take the usual 10 GHz horn and extend its sides in both the vertical and horizontal planes.

The formula is: $4\pi AB/\lambda^2$
(where A & B are the final aperture dimensions). Figure 2 describes the shape of the horn.

Construction

The local metal shop at the college that I teach ham classes at came up with some 5052 aluminum sheet. At 0.062" thick, it's just rigid

enough to hold its shape out to an exit opening of about three feet on a side—just enough room to fit into my station wagon's rear hatch opening.

We fabricated two sheets of aluminum into shape using a pattern press break for nice tight corners. We then manipulated both sections into place for a perfect extension of a small 10 GHz horn that gave us good results in earlier tests. We confirmed our measurements using the RSGB formula (see above).

The next step in the fabrication of the super horn was to heli-arc the two halves together at 10,000 degrees, using 5356 welding stock. Sanding cleaned up the joints for a smooth finish on the inside surfaces. We held our breath to make sure the entire horn would keep its shape without distorting under its own weight. It held up fine with little warp.

We attached a waveguide feed assembly, patterned after our small-horn sample. A small file gave us an almost perfect match to the WR-90

Figure 2. Dimensions and calculations for the 10 GHz Super Horn antenna. The horn formula appeared in the *RSGB VHF/UHF manual*.

The 23-Foot Indoor Antenna

Make an effective 20 and 80 meter apartment-dweller antenna.

by Richard Q. Marris G2BZQ

Relocating into an apartment for the first time can have a very traumatic effect. This, of course, also applies to any other habitation where an HF outdoor antenna is not permitted or is physically impossible to erect.

This first happened to me (licensed for too many years to remember how many) when, over 30 years ago, new employment meant moving the QTH at regular intervals, and turned me into an apartment dweller. Since then I've tried and evolved many apartment antenna types, including loops and helicals.

My Solution

With just 23 feet of wire across a room, it is possible to quickly get onto 20 and 80 meters in a minimum of time and at minimum cost.

In each successive QTH move, the good old 23 feet of wire has always been used first, to get G2BZQ back on the air again within a few hours of taking up the new residence.

Figure 1 shows the 20 meter version, and Figure 2 that for 80 meters. Note that the same 23 feet of wire (A-B) is used for both bands. Assuming that your transceiver can be placed in the corner of a room, A-B will consist of a drop down of about four feet to your rig, and the remaining 19 feet will be hung horizontally diagonally across the room, at least 9" below the ceiling. White PVC covered stranded hookup wire (#22 gauge—Radio Shack #278-1218) should be used as it is inconspicuous against a white ceiling. It should be supported by nylon fishing line which is also inconspicuous.

This antenna should be kept away from electrical wiring, water pipes, etc. Terminate with a small plastic ring at point B, leaving about 2" of bare wire hanging down. Support the plastic ring to the room corner with 10 lbs. breaking strain nylon fishing line. At the other corner of the room, support the wire to that corner with fishing line, leaving a drop down at A (about four feet), which is near the transceiver. This is the 23-foot antenna!

For 20 Meters

See Figure 1. As an antenna wire is increased in length above $1/4$ wavelength long, the terminal impedance increases to a

Figure 1. A 23-foot indoor antenna for 20 meters: 1a) 20 meter antenna; 1b) 20 meter helical ground.

point where the impedance reaches 50 ohms. Unfortunately, at the same time the reactance has also increased, but can be tuned out with a series capacitor (C in Figure 1a). This variable capacitor should be a good quality ceramic type, of equivalent size to that in your transmitter's PA. It should be mounted in a plastic box with a large diameter plastic instrument knob. Coaxial socket SKT1 can be connected to a 50-ohm output having a pi network output, using a short length of RG58 feedline. Better still, an existing 20 meter antenna tuner (ATU) can be inserted between SKT1 and the rig. This will help eliminate TVI.

For 80 Meters

Figure 2 shows that the same 23 feet of wire is used for 80 meters, with the addition of a vertical end helical coil L2 which, in fact, is a combined loading coil and radiating element added to the end of the 23-foot wire (A-B).

Using 22' 6" of the same PVC covered wire, wind 21 turns helically on a $1/2$ " diameter wood dowel or plastic tube, spacing the turns over a width of 3' 8". A tail of 18" will be left at the top end and, fitted with a strong clip, it can be attached to the main antenna wire at point B. It will be necessary to fit a suitable wood base to hold L2 vertically.

Figure 2. The indoor 80 meter antenna.

FEEDBACK

In our continuing effort to present the best in amateur radio features and columns, we recognize the need to go directly to the source—you, the reader. Articles and columns are assigned feedback numbers, which appear on each article/column and are also listed here. These numbers correspond to those on the feedback card opposite this page. On the card, please check the box which honestly represents your opinion of each article or column.

Do we really read the feedback cards? You bet! The results are tabulated each month, and the editors take a good, hard look at what you do and don't like. To show our appreciation, we draw one feedback card each month and award the lucky winner a free one-year subscription (or extension) to 73.

To save on postage, why not fill out the Product Report card and the Feedback card and put them in an envelope? Toss in a damning or praising letter to the editor while you're at it. You can also enter your QSL in our QSL of the Month contest. All for the low, low price of 29 cents!

The 23-Foot Indoor Antenna

Continued from page 16

At the transmitter end of the antenna wire, a simple LC ATU matches the antenna to your rig. The ATU should be built into a metal box. L1 consists of 14 close-wound turns of 18-gauge enamel copper wire, wound on a 1.2" diameter PVC form. L1 should be mounted in the metal box with at least a coil diameter of clearance away from metal work. C1 should be a good quality variable capacitor of 300 pF capacity, or even 500 pF.

The simple ATU consists of L1 + C + SKT1, in a metal box. However, an existing good LC, "T" or other ATU, could be used in place of the one shown.

Wire length A-B, plus the vertical helical section L2, form the radiating antenna. L2 should be mounted vertically and fitted with a wood base to support it—it should be at least 15" clear of walls, etc.

Ground Systems for 20 and 80 Meters

Ground connections are an ongoing problem with the indoor antenna. If there is a metal water pipe close to the TX, then a short wire stout flex can be clipped to it to form a ground. Do not connect to a plastic water pipe, gas pipes or electric wiring conduit. On 20 meters, the connecting lead should not exceed about six feet, and on 80 meters up to 15/20 feet should be satisfactory.

Figure 1b shows an artificial ground for 20 meters. It consists of 36 feet of PVC covered stranded wire (Radio Shack #278-1218) helically wound around a six-foot length of 5/8" diameter dowel of plastic pipe. The turns should be spaced to fill a length of 5'5" on the dowel. The ends of the winding can be secured with tape. The connecting lead should be four feet long. The artificial ground should not be laid on the floor, but provided with supports at least 24" high and mounted horizontally. Various positions relative to the antenna should be tried for the best results.

I developed an excellent artificial ground for 20/80 meters when living in Minneapolis in the 1970s. The operating position was near a very large metal-framed double-glazed window. A short ground lead was clipped to the metal window frame and proved to be most effective on both 20 and 80 meters. I have since tried this idea at other locations. No doubt it formed a vertical ground plane.

Conclusion

This simple 23-foot antenna gives an apartment dweller a quick and effective way of working on the 20 and 80 meter bands. Of course, the higher the antenna the better the results. I have worked DX on 20 meters using both 10 and 100 watts CW, and up to about 3,000 miles on 80 meters. However, in the interests of domestic safety and TVI elimination, a low power TX is suggested—no more than 20 watts.

Accurate Low Cost VSWR Meter

Convert this CB accessory for 1.8-450 MHz operation.

by Phil Salas AD5X

Nothing beats a good VSWR meter when it comes to playing around with new antenna designs. Unfortunately, meters that work up to 450 MHz can be quite expensive. This article describes simple modifications that can be made to popular CB-style VSWR meters to enable them to accurately perform up through the 3/4-meter ham band.

The Meter

Figure 1 shows a popular CB-type VSWR meter. Made by many different manufacturers, they use an internal directional coupler. They were very popular up until a few years ago when the transformer type VSWR meter became more popular (undoubtedly due to their lower manufacturing cost). The CB-type meter is widely available at swap fests, and can be had for very little money. I paid \$5 for mine at one of our local electronic sidewalk sales.

Upon getting home with this unit, I opened it up and was very impressed with

the quality of the coaxial coupler itself. The total internal coupler length measured five inches. For best performance, a directional coupler should be less than a quarter wavelength at the highest frequency used. A quarter wavelength at 450 MHz is about six inches, so it appeared there was some potential here. Unfortunately, the internal components had very long lead lengths and were poorly dressed. Sure enough, a precision 50 ohm load measured with this meter showed a 2:1 VSWR at 146 MHz, and a 2.8:1 VSWR at 445 MHz. Obviously, this would not do.

Modifying the CB-type Meter

Figure 2 is an internal drawing of the VSWR meter. The first thing I did was remove the detector diodes, 150 ohm terminating resistors, and bypass capacitors. I then cleaned out all excess solder. Next, I made new bypass capacitors by paralleling good rectangular ceramic 0.001 and 0.01 μF capacitors, as shown in Figure 3. The 0.01 μF capacitor is a good bypass at lower frequencies, and the 0.001 μF capacitor is a good bypass at higher frequencies. Mount these capacitors directly to the terminal strips at either end of the coupler, attempting to make the lead lengths as close to zero as possible.

Then I put in new 1/4 watt 150 ohm resistors, as shown in Figure 2. Orient these resistors so as to minimize lead length. Also, position the resistors so that the lead lengths are identical on both resistors. It doesn't matter too much if there is some lead inductance, but it's important that the lead inductance on both resistors be the same.

Next, I put in two new 1N34A detector diodes (available from Radio Shack) as shown. Again, orient the diodes for minimum lead length and ensure that the lead length on both diodes is the same.

That's all there is to it. Now for some measurements.

The Results

For my test loads, I again used my 50-ohm precision termination, a 75 ohm F-type termination with a F-to-PL-259 adapter, a home-built 100 ohm termination, and the Radio Shack RS 21-506 15 watt DC-500 MHz dummy load. The 100 ohm termination was built by sliding a 1 watt 100 ohm metal oxide resistor (RS 271-152) into a RG-6 F-

Figure 1. The once-popular CB-type VSWR meter.

Figure 2. An internal view of the VSWR meter, showing the components to replace.

Results at 445 MHz		
	Measured VSWR	Expected VSWR
50 ohm precision load	1.05:1	1:1
50 ohm 15 watt RS load	1.10:1	1:1
75 ohm TV termination	1.50:1	1.5:1
100 ohm termination	1.80:1	2:1

Figure 3. Making new bypass capacitors.

56 connector (RS 278-214). A 1 watt resistor fits perfectly into this connector, and a 1/2 watt resistor fits perfectly into the RG-59 F-59 connector (RS 278-211). The measured results at 445 MHz were as shown in the table.

Not bad! These results are certainly accurate enough for virtually anything most hams would want to do. Also, I was able to get a full-scale forward meter deflection at 450 MHz with only a quarter watt of transmit power.

I have described a means of modifying a common variety CB-style VSWR meter such that it becomes virtually a precision VSWR meter up through 450 MHz. The price is right and you'll have a piece of test equipment you'll be proud of.

An Effective 160 Meter Antenna

How to build one on a small residential lot.

James S. Stanley KA6MMQ

Since the time of the year had arrived when low frequency propagation characteristics are improving, my attention turned to finding a way to erect an effective yet low profile antenna for 160 meter operation. Since we live on a small residential lot, approximately 100 feet by 100 feet square, my options were limited. After reviewing a few designs from several antenna reference books, it looked as though the "inverted L" Marconi antenna was going to be the only practical choice given the space available.

The Marconi L-Type

A typical Marconi L-type antenna consists of a wire which is 1/4-wavelength overall at the desired operating frequency. The length in feet is determined by the formula:

$$\frac{234}{F_{\text{MHz}}} = \text{length (feet)}$$

The usual installation of a wire inverted L antenna for 160 meter operation consists of two support poles or other structures spaced approximately 100 feet apart. Both supports need to be 30 to 40 feet overall in height. Figure 1 shows a vertical elevation sketch of the typical L-type antenna. Note that a single wire is used to form the radiator portion of the example antenna.

I chose to use steel mast tubing, sold by Radio Shack in 10-foot lengths, to act as

the end supports for the antenna system. The feedpoint had to be located near the back corner of our property so I used the inside wall of the concrete block fence which surrounds our back yard to act as the only support for the 30-foot mast. After drilling the concrete wall and installing expansion bolts, I used two 1-1/4" electrical conduit clamps to fasten the mast to the concrete. The installation is simple: The conduit clamps hold the mast tightly against the wall up to approximately seven feet above ground level. The masts have sufficient tensile strength so as to not break. They do, however, flex a bit in the wind. The other 30-foot mast is anchored to the outside wall of our house. A standard mounting kit was used for the support. Neither mast has any guy wires or ropes attached to it for stabilization—it simply was not necessary.

As you can see from Figure 1, ground radial wires are required in order to achieve satisfactory performance from the typical L antenna. In many cases like mine a few radials can be installed but the number and length are somewhat limited. The basic rule of thumb is to install as many as possible that are 1/4-wavelength long at the frequency of interest. My antenna system has two radials that are 135 feet long and several more that are shorter. You may want to bury the radials to protect them.

After erecting the wire as shown, I made

several resistance/reactance measurements at frequencies between 1.800 MHz and 2.000 MHz by using an RF impedance bridge connected to the feedpoint of the antenna. I used a General Radio model 916A RF bridge, along with a General Radio 1211-C unit oscillator as a signal source. I also used a Kenwood model R-2000 receiver as the null detector for the test setup. The results showed that the feedpoint resistance was generally quite low, approximately 10 ohms resistance at the band center, which is 1.900 MHz. This presented a very poor match for the HF transceiver used at my station. I might add that since I use one of those newfangled units with a solid-state output stage, the transceiver is designed to fold back or limit output power if the SWR is in excess of 1.5:1 in order to protect the output transistors from damage. I considered using a tuner, but since the coax cable between the operating position and the antenna feedpoint was rather long, the performance and bandwidth in this particular instance would be quite poor. Some consideration was also given to installing a remotely-controlled matching network at the antenna feedpoint and running the control wiring back to the operating position. This option seemed too complicated. What we really needed was a 50-ohm input impedance for the antenna so that standard RG-8 U coax could be used between the antenna and the operating position, where

Figure 1. Single-wire Marconi "inverted L" antenna.

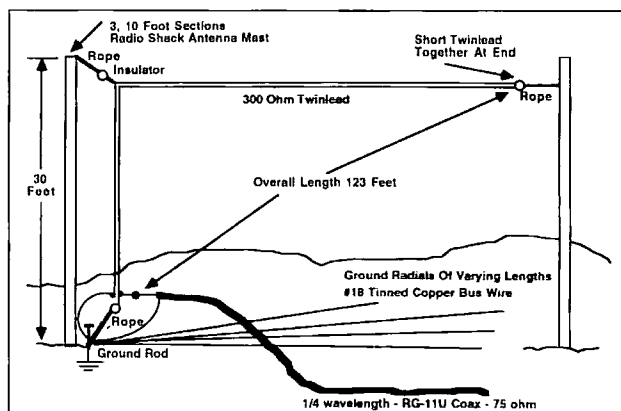

Figure 2. 300-ohm twin-lead Marconi "inverted L" antenna.

the transceiver was located.

The Twin-Lead L Antenna

After some additional investigation, I found a design for an L-type antenna to be constructed from 300-ohm TV-type twin lead. The physical dimensions were to be approximately the same except the twin lead was to be used to form a loop, similar to a folded dipole. The far end of the twin lead was to be shorted together and one end of the loop connected to ground at the feedpoint, while the other wire was to receive the power from the transceiver. Figure 2 shows a diagram of the "twin-lead L" antenna. The theory of this type of system is that the twin lead acts as an impedance transformer which increases the "radiation resistance" of the antenna, which in turn helps overcome the inherent ground system losses. The result is a more efficient antenna and a higher feedpoint impedance.

After disassembling the antenna shown in Figure 1 and replacing it with the twin-lead antenna shown in Figure 2, we repeated the resistance/reactance measurements and found that the numbers had changed significantly from the original single-wire unit. The following results were noted:

Frequency	Resistance	Reactance
1.800 MHz	110 ohms	-152 ohms
1.900 MHz	100 ohms	-3 ohms
2.000 MHz	190 ohms	+144 ohms

While these values depart from the ideal 50-ohm figure required for optimum transceiver match, they represent workable parameters which can be transformed to 50 ohms. It would be expected that the impedance measurements obtained would vary somewhat from one installation to another; however, in my case, the center of the band at 1.900 MHz measured 100 ohms resistance with a small amount of capacitive reactance. A review of transmission line theory shows us that a 1/4-wave-length section of transmission line, when presented with a load other than the nominal impedance of the line, will act as an impedance transformer under the mismatched condition. The impedance inverting property of the line provides a good match between a high-impedance circuit and a low-impedance one. I had some RG-11 U coaxial cable

on hand which has a nominal characteristic impedance of 75 ohms and decided to put that to a good use. A quarter wavelength of the RG-11 U can be calculated by the formula:

$$1/4 \text{ wavelength} = \frac{246}{F_{\text{MHz}}} \times 0.66$$

In this equation, the value 0.66 represents the velocity factor of the transmission line, which provides a correction for the line propagation characteristics when compared to propagation of the radio wave in free space. In this case, I wanted to optimize the antenna for 1.900 MHz and have minimal SWR present at the edges of the band, which are 1.800 MHz and 2.000 MHz. So what we are really talking about is trying to make the transceiver operate across 200 kHz of spectrum. The actual length of RG-11 U coaxial cable worked out to be 85.4 feet. The cable was installed as shown in Figure 2 and the resistance and reactance measurements were repeated for the three frequencies previously outlined.

This time the antenna bridge was looking at the antenna through the 75-ohm cable. The following results were noted:

Frequency	Resistance	Reactance
1.800 MHz	17 ohms	+18 ohms
1.900 MHz	56 ohms	+2 ohms
2.000 MHz	18 ohms	-9 ohms

Due to the physical layout of my ham shack in relation to the antenna and feedpoint, I needed approximately 120 feet of coaxial cable to get to the transceiver from the antenna so I decided to coil up most of the 75-ohm matching section and then install 52-ohm RG-8 U coaxial cable. Again the velocity factor was 0.66. I was a bit apprehensive about the potential attenuation from coaxial cable lengths this long; however, after consulting one of my textbooks, I determined that the worst case loss was 0.45 dB at 2.0 MHz, assuming a matched condition and a total cable length of 205 feet for the RG 11 and RG 8 types. This means that for 100 watts out of my transceiver, 90 watts would arrive at the antenna. After the installation of the coaxial cable to the operating position was complete, I again connected the antenna bridge and noted the following measurements:

Figure 3. Smith chart showing SWR versus frequency measurements taken at the operating position.

normalized the figures shown above for 50 ohms and plotted them on a Smith chart (see Figure 3) with a 1.5:1 and 2.0:1 SWR circle also drawn on the graph. As you can see in this chart, a substantial portion of the band falls within the 2.0 region, and approximately 40 kHz either side of the band center at 1.900 MHz falls within the 1.5:1 region. This means that from 1860 kHz to 1940 kHz my solid-state transceiver will produce full output power without any additional antenna tuner or ATU.

Program to Predict Impedance

The Marconi L antenna characteristics can vary greatly from one installation to another. It should be understood that, depending upon the resistance and reactance of the antenna feedpoint, it may or may not be necessary to use exactly 1/4-wavelength or -90 degrees of transmission line in order to obtain a satisfactory match. The matching section could be longer or shorter for optimum results.

Since a certain portion of this project could result in tedious trial-and-error cutting of coaxial lines, given the variables involved from one installation to another, I decided prior to beginning the work to write a simple computer program in BASIC to predict the resulting impedance at one end of the transmission line when the other end is terminated with an impedance other than the nominal characteristic impedance of the line.

See Figure 4 for the program listing. If you care to enter the program codes for yourself, it should only require a few minutes of time. Also, I have uploaded the program to the 73 BBS so that it can be downloaded for your use. The program is titled "Mismatched Transmission Line" and will operate on any IBM compatible computer. I should point out that the program and the matching/impedance transformation technology is applicable at any of the amateur HF frequencies you might be interested in.

Matching Network Circuit

Now for a very simple yet effective matching network which will enable you to operate across the entire band from 1.800 to 2.000 MHz without making adjustments. That's right, no knobs to turn or tweak!

The circuit shown in Figure 5 has a basic ATU consisting of a single series inductor with two fixed shunt capacitors, either of which can be selected by switch S2. When operating in the bypass mode the unit is out of the circuit and, as I mentioned earlier, the transceiver will put out full power from 1860 kHz to 1940 kHz. If operation below 1860 kHz is desired, the ATU is switched in circuit and switch S2 is placed in the 1.8 MHz position. If operation above 1940 kHz is desired, switch S2 is placed in the 2.0 MHz position. It is important to understand that the design criteria for this circuit was only to keep the SWR at substantially less than 1.5:1 at all portions of the band, not to effect an absolute 1:1 match at any frequency.

If you examine one of the many graphs published in the various antenna textbooks, it is evident that the loss in transmitted power at an SWR of 1.5:1 is only 4%. That amount of loss is insignificant and will produce no perceptible change in the received signal from your station. If you must have a 1:1 SWR at whatever frequency you happen to be operating on, I suggest you use a standard ATU or transmatch, such as the SPC design. These are described in various antenna textbooks and are also for sale commercially from several equipment manufacturers. In that case, you may omit this ATU from the circuit. The ATU is designed to handle 100 watts CW or RTTY continuously, without heating or other problems. However, if you plan to operate with power levels in excess of 100 watts, you may wish to construct the matching network with components that have a higher voltage and/or current rating.

Construction Techniques

As far as construction techniques go, I constructed my ATU on a small metal plate and mounted it on the wall of my shack so that it was out of the way. If you want to get fancy, you could put the circuit in a metal box with coax connectors.

There you have it, operation across the entire 160 meter band, with no remote motor controlled antenna matching units or other complicated devices. In fact, most of the matching is accomplished by the selection of coaxial cable lengths and types. The coaxial cable is a necessity in order to connect the antenna feedpoint to the transceiver, so why not let it solve the impedance matching problems also? The RF impedance bridge and oscillator I used to make the resistance and reactance measurements were purchased surplus for a modest price. There are also several new solid-state units on the market which have the generator and detector self-contained; one even has a frequency counter built into it.

One last note: I have enjoyed many contacts on 160 meters since installing this antenna and matching system. At night, I am consistently able to work other stations all over the country and receive good signal reports, with only 100 watts out of the transceiver.

The "Simplest Transverter"

Check out the 6 meter band with this inexpensive 2 meter interface.

by Bob Witmer W3RW

Interested in trying a new band at minimum expense? Here's a receiving and transmitting converter (transverter) that requires no operating power (other than local oscillator DC) or T/R switching for operation, and will provide a minimum communications capability for checking out a new band such as 6 meters using a 2 meter transceiver.

While checking out the latest Mini-Circuits Labs catalog I was impressed by a new family of low-cost, high-level double-balanced mixers (DBMs): TUF-1H, TUF-2H and TUF-3H. With this in mind I decided to see how simple a transverter could be made. To simplify the design, I selected operation using the 6 and 2 meter bands and a 90 MHz LO. The high level DBM provides a useful output power level even though it is still on the low side (but not as low as the output of a standard level DBM, which is approximately 20 times lower). In addition, the transverter will work with FM, SSB and CW modes.

What is it? Well it really is nothing more than a high-level double-balanced mixer (DBM) with an attenuator on the transceiver side, an output low-pass filter on the antenna side, and a local oscillator (see Figure 1).

As mentioned before, this approach is practical because the high-level DBM's linear power capability goes all the way to 25 milliwatts. Without the need for any additional power (other than the local oscillator) you can get an output that is approximately 5 milliwatts—the actual power depends on a variety of factors. Measured transverter output using a HP 431D power meter was 5.1 milliwatts at 52.29 MHz. The other mixer characteristic that makes the simplest transverter possible is the DBM's bidirectional capability: The RF and IF ports can be interchanged, allowing mixer operation to

occur in either direction.

Five milliwatts—you've got to be kidding! Now, before you laugh too much about that power level, consider that one well-known popular 2 meter hand-held transceiver has a 100 milliwatt low power position (one new 2 meter transceiver even has a 20 milliwatt position!) and that when used with the normally supplied inefficient "rubberduck" antenna, which typically has anywhere from a 6 to 10 dB loss factor relative to a dipole, the resulting radiated power could be on the order of 10 to 25 milliwatts—only several dB higher than 5 milliwatts. In addition, since the free-space line-of-sight path loss at 53 MHz is approximately 9 dB less than the loss at 146 MHz, if that 5 milliwatts is connected to a dipole or better equivalent antenna, communications similar to low power 2 meter hand-held operation is possible. This power level should make the FCC happy!

Receive Performance

If the transverter is used with a 2 meter transceiver with a 500 mW low power output, a 13 dB attenuator is needed on the input to limit the power to the linear operating range of the DBM. In this case, the total loss during receive is the conversion loss of the DBM—7 dB, plus the 13 dB loss of the attenuator pad for a total loss of 20 dB—equivalent to reducing the signal to 1/10 of its value. If your 2 meter receiver sensitivity is 0.2 μ V then a 20 dB loss in front of the receiver will be equivalent to using a 2.0 μ V receiver—which is not really all that bad considering the stations you can work using a 5-milliwatt!

In actual practice I've had QSOs on simplex and through several local 6 meter repeaters using only 2 milliwatts—approx-

mately half as much power! In all honesty, my signal was noisy, but it was fully intelligible.

My antenna is a Cushcraft Ringo at 25 feet, fed through about 30 feet of RG-8/U. Considering the simplicity of the transverter, the performance was surprising! If you operate CW or SSB, greater performance will be obtained. Figure 2 shows the transverter losses during transmit and receive.

How It Works

Receive: During receive, 6 meter antenna signals are connected via the low-pass filter to the DBM, where they are mixed with the 90 MHz local oscillator injection. The transverter acts as a typical receive converter. The local oscillator's output passes through the input attenuator to the 2 meter rig.

Transmit: The 2 meter rig's low power transmit signal is fed through the attenuator, where it is reduced to a level acceptable to the DBM and passed to the DBM. The 2 meter signal is mixed in the DBM with the 90 MHz LO creating outputs in the 6 meter band and in the 230 MHz region. The output of the DBM is connected to the low-pass filter, which passes the 6 meter signal and attenuates the 230 MHz output and any 2 meter and local oscillator signal feed-through.

Detailed Operation Description

The following sections provide a detailed description of the transverter's operation and refer to Figure 3, the schematic diagram.

Input Attenuator: The input attenuator of the transverter was designed for a 1/2 watt 2 meter power level, using approximate resistor values from the ARRL Handbook's 50 ohm resistive attenuator table, to provide ap-

Figure 1. Simplest Transverter diagram.

Figure 2. Transverter section loss diagram.

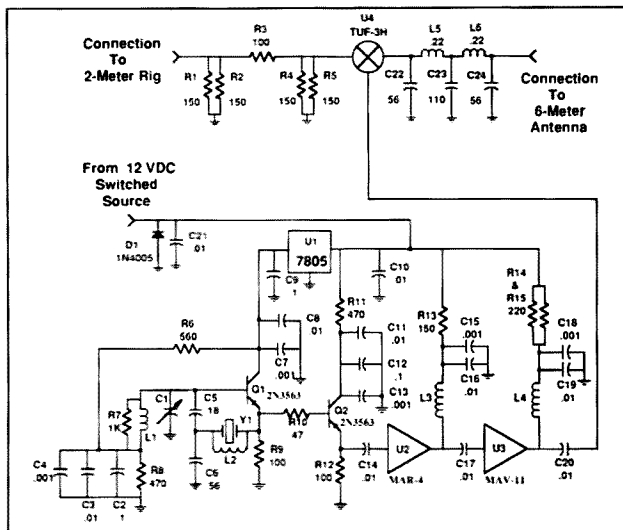

Figure 3. Simplest Transverter schematic.

proximately 13 dB of attenuation. This reduces the 1/2 watt to the recommended maximum linear rated input of the DBM, 25 mW. The input and output sections of the attenuator are made up of two paralleled 150 ohm 1/2 watt resistors.

Mixer: As mentioned before, the transverter takes advantage of the DBM's bidirectional performance characteristic. The DBM's ports are matched to the appropriate frequency range sections of the transverter. The IF or lowest frequency port (Pin 2) is used as the 6 meter port. The LO output is connected to the "LO" port (Pin 4) and the 2 meter side is connected to the "RF" port (Pin 1). Pin 3 of the DBM is connected to case ground and does not need a separate connection if the case is grounded.

Local Oscillator: The 90 MHz local oscillator circuit is adapted from the July 1989 *QST* article, "A Clean, Low-Cost Microwave Local Oscillator," by Richard Campbell. Mini-Circuits Labs MAR-4 and MAV-11 MIMICs are used to provide the +14 to +17 dBm injection needed for high-level DBM operation. The circuit will "free" oscillate with a 47k resistor in place of the crystal and L2. This can be used to get the oscillator L1 and C1 components on

frequency to insure crystal oscillation. L1 is non-critical. One approach is to experiment until you get a coil that gives you the desired frequency oscillation range when tuned with C1. When the free-run frequency tuning range covers the crystal frequency, remove the 47k resistor and install L2 and the crystal, then adjust C1 for reliable starting and fine frequency trimming.

Local Oscillator Frequency Selection

FM & Repeater Band Segment Operation:

A 90 MHz 5th overtone crystal. Y1, was chosen for the oscillator so that the receive range for 53 to 54 MHz would convert to 143-144 MHz to simplify frequency readout. Many of today's 2 meter rigs will operate, or can be modified for full operation, down to 142 MHz, permitting this approach. If your rig will

not make this range, I would recommend using a 93 MHz crystal. This will convert the active 6 meter repeater output section of the band (usually the lower half of the 53.01 to 53.97 MHz range) to the repeater input/simplex section of the 146 to 147 MHz band.

CW & SSB Band Segment Operation: Operating the Simplest Transverter with a 94 MHz oscillator will translate 144 MHz to 50 MHz for weak signal work but would convert the 6 meter repeater outputs to the low end of the 147 to 148 MHz range—the repeater output

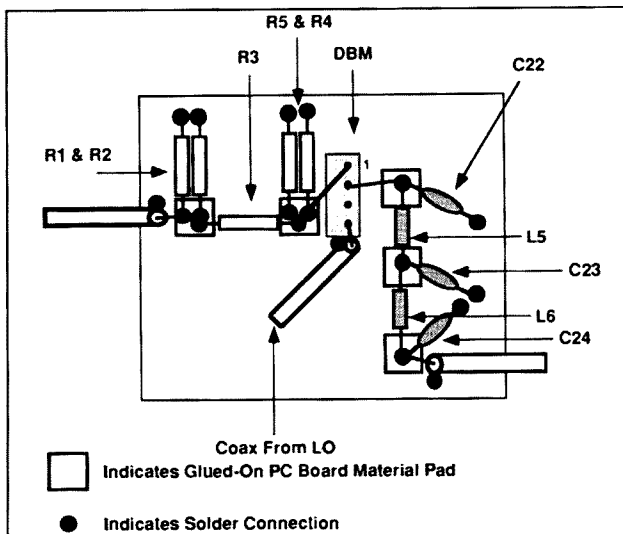

Figure 4. Approximate layout of mixer/filter board (not to scale).

Figure 7. Simplest Transverter diagram for 10/40 meter operation.

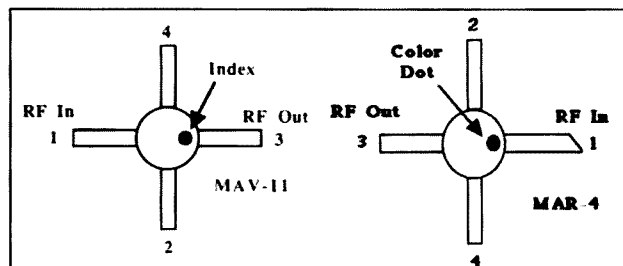

Figure 8. Pin identification of the MAV-11 and MAR-4 MMICs.

section of the 2 meter band. Local 2 meter repeater signals are often strong enough that some bleed-through is noted during base operation with an outside antenna if you use this frequency plan.

Output Filter: Because of the translator's frequency plan and the low output power level, filtering requirements are not severe. The 6 meter side of the DBM is connected to a five-element low-pass filter (L5, L6 C22, C23 and C24) whose values were selected from the five-element low-pass filter table in the *ARRL Handbook*, targeted at a 3 dB corner at 60 MHz with 20 dB attenuation at 83 MHz and 40 dB at 125 MHz.

Construction, Check-Out and Operation

The Simplest Transverter was constructed in two parts to simplify assembly and check-out—the input attenuator/DBM/output low-pass filter and the local oscillator. Both were assembled by gluing small pieces of single-sided board material, cut to the size required for the connection pads, onto a double-sided G-10 circuit board where desired. If a change is required, you can pry the desired pad loose and glue it in the new location. Grounding is accomplished by soldering directly to the ground plane—keeping the RF circuit ground leads as short as possible. Feed-through bypass capacitors are used for bypass requirements and DC power distribution is done on the opposite side of the board. Figures 4 and 5 show approximate layouts.

As mentioned before, local oscillator operation can be checked with a broadcast FM radio. With the LO operating, the transverter can be used as a receive converter for initial check of operation. An FM broadcast receiver (tuned to the second harmonic) can also be used to monitor the output of the transverter during transmit.

When operating with the transverter, use your 2 meter rig just as you normally would (in low power position). Program CTCSS and repeater split parameters as required if repeater operation is intended.

Higher performance can be achieved by adding receiver and transmit amplification stages to the transverter. Figure 6 shows one way that this could be accomplished.

Other Bands

The Simplest Transverter approach can be applied to other frequency band combinations. One example of this is shown in Figure 7, where the Simplest Transverter approach is used to provide 40 meter capability using a 10 meter transceiver. Of course, the input attenuator value and the low-pass filter characteristics must be adjusted, as required, for different power levels and operating frequencies.

Only slightly more complex than a receive converter, the Simplest Transverter provides about the simplest way to obtain operation on 6 meters with a 2 meter rig—any mode. This same approach can be used to obtain similar results on other ham bands.

Many thanks to all those who've had their ears abused by my noisy signals during QSOs while checking out the ability to conduct practical communications with milliwatt level transmit power.

Stretch Beam?

It was Sunday morning of Field Day. The sky to the east showed color as 40 meters turned scratchy. I switched to 20 CW. There was an SM calling CQ. Why not see if he could hear my 4 watts? He did. I called CQ and worked DL and JA. No one else was working DX. Funny what happens when you have a StretchBeam.

Build the Tone Processor

*Eliminate interfering signals with this versatile
switched capacitor audio filter.*

by Kazuo Niwa JA1AYO

The tone processor described here uses the National Semiconductor MF4, a four-stage Butterworth low-pass filter. As Figure 1 shows, unlike conventional audio filters, the capacitor filter cutoff f_c can be changed by varying the clock frequency f_{clk} . There are two varieties of MF4 switched capacitor filters, the MF4-100 and the MF4-50. The MF4-100 is shown in Figure 1. For the MF4-50, the relationship between the cutoff frequency

and the clock frequency is $f_c = f_{clk}/50$. Referring to Figure 1, the input impedance Z_{in} is 3 megohm for a f_c of 3 kHz and 20 megohm for a f_c of 500 Hz. The SCF has an ideal filter gain of around about 1. Attenuation for a four-stage filter is 24 dB per octave.

The MF4-100, an 8-pin DIP package is used in this tone processor. The cutoff frequency f_c varies from 500—3000 Hz and f_{clk} varies over a range 100 times

greater between 50—300 kHz. Two MF4s are used in series to create an eight-stage low-pass filter in order to achieve greater attenuation.

Once power supply connections are made, a frequency counter can be connected to terminal TP as shown in Figure 2 to measure the clock frequency f_{clk} without affecting the oscillator frequency. As variable resistor VR is adjusted, the cutoff frequency f_c and clock frequency

Photo A. Remove interference with this versatile switched capacitance audio filter.

Photo B. Inside view of the tone processor.

Photo C. The completed PC board.

Photo D. Chopping of the waveform by the clock signals can be observed.

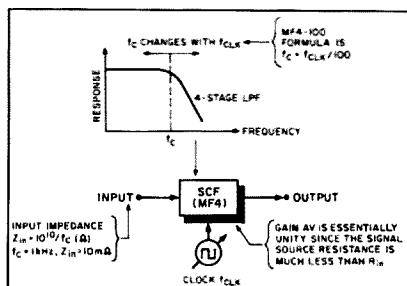

Figure 1. A switched capacitor filter (SCF) can be made using the MF4-100.

f_{clk} for an 24 dB/octave four-stage low-pass filter and a 48 dB per octave low-pass filter vary as shown in Figure 2b. This tone processor is very effective in removing unwanted noise from SSB signals.

Circuit Description

The final version of the tone processor, shown in Figure 3 and Figure 4, is designed chiefly for improving SSB reception, so low-pass filters (using the SCF ICs) as well as high-pass filters are used to provide audio balance. An LM358 op amp Chebyshev active filter with f_c fixed at 300 Hz has three stages and 18 dB/octave attenuation. An audio amplifier follows the high-pass and low-pass filters to drive a speaker.

The circuit shown in Figure 4 should be connected to a 12-volt power supply. An 8-volt three-terminal voltage regulator is used to ensure that the voltage supplied

to the MF4s holds steady to ensure clock frequency f_{clk} stability. ICI, a LM358, shown in Figure 5, is composed to two op amps: One is a three-stage Chebyshev high-pass filter; the other provides a $1/2 V_{cc}$ output which is used by the MF4s.

The high-pass filter uses fixed RC passive type components to set the clock frequency, but the two MF4s of the eight-stage low-pass filter use variable resistors to change the low-pass filter clock frequency.

The National Semiconductor ICs are available through Digi-Key Corporation (800-344-4539) and other sources. The

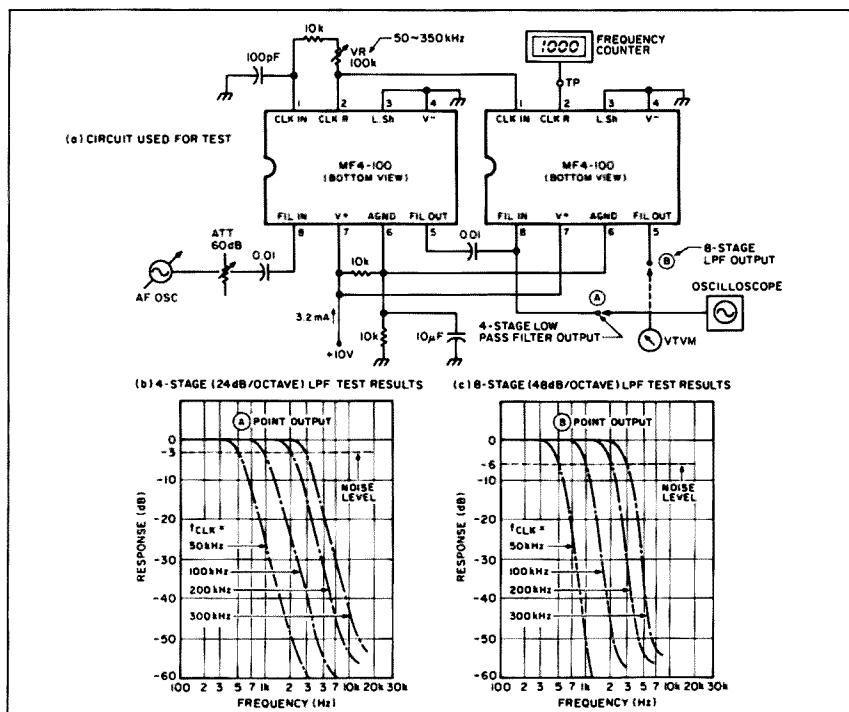

Figure 2 (a). Prototype 4-stage and 8-stage Butterworth low-pass filters. (b). Frequency response for the 4-stage filter. (c). Frequency response for the 8-stage filter.

Toshiba TA7368 audio amplifier IC is available from MCM Electronics, 858 E. Congress Park Dr., Centerville, OH 45459-4072; Telephone: (800) 543-4330 or (513) 434-0031.

Printed circuit patterns for the circuit boards and the circuit layout are shown in Figure 6. Place a pin in the circuit board hole marked test point (TP). Photo A shows the completed tone processor in its case. The frequency characteristics of the tone processor where the cutoff frequency f_c is set to 2 kHz are shown in Figure 7. The upper and lower slopes of the curve illustrate the difference in the characteristics of the low-pass Butterworth filter and the high-pass Chebyshev filter. The circuit board can be put in a project box, as shown in Photos A and B, with two rotary variable resistors on the front panel to control the cutoff frequency of the low-pass filter and the volume, as well as an on/off switch.

Operation

Put the tone processor between a transceiver and external speaker. If the tone processor is OFF, then the speaker line simply runs through the tone processor unaffected. Use insulated wire on the

Note 2: The Toshiba TA7368 audio amplifier IC is available from MCM Electronics, 858 E. Congress Park Dr., Centerville OH 45459-4072. Telephone: (800) 543-4330 or (513) 434-0031.

Note 3: All other parts should be available from Digi-Key Corporation at (800) 344-4539 or Mouser Electronics at (800) 346-6873.

run from VR1 to avoid frequency changes—putting your finger near that wire is enough to shift the clock frequency. The frequency markings on the cutoff frequency control as crowded in the upper range are shown in Photo A. This problem could be solved by a D curve variable resistor, but they are hard to get.

While listening to 40 meter SSB with the tone processor, much unwanted noise could be eliminated by adjusting VR1. For SSB a cutoff frequency of about 1000 Hz proved to be the best for reducing noise; below that frequency, intelligibility suffers. The tone processor generally improves readability 4 signals to readability.

The Down East Microwave WSSK

Microwave weak signal source kits.

Down East Microwave

RR1, Box 2310

Troy ME 04987

Telephone: (207) 948-3741

Fax: (207) 948-5157

Price Class: Complete kit, \$65; assembled board, \$88; assembled in a box, \$120.

To paraphrase a current beer commercial, "Wouldn't it be great if someone made a simple, reliable and inexpensive signal source for the microwave bands?" Well, someone does, and they're called the WSS903K, WSS1152K and WSS1296K kits from Down East Microwave. All three kits can be assembled in one evening (if you're so inclined) and feature on-board interdigital filters, MMIC stages for stability, and a no-tune design.

How They Work

All three sources use a two-stage oscillator/buffer, working anywhere from 90 to 110 MHz, followed by an MMIC amplifier, diode multiplier and two additional MMIC amp stages. Output is typically in the 1-to-3-milliwatt range, which is more than adequate for aligning preamps and mixer stages. The WSS903K is designed for an output frequency of 903.100 MHz using a crystal frequency of 90.3100 MHz, while the WSS1296K pops up at 1296.100 using a 108.0833 fundamental. On the other hand, the WSS1152K is probably the most versatile of the three, with

usable harmonics all the way up to and including the 3 cm band (10.368 GHz). It can be used at 2304, 3456, and 5760 MHz as well, and for just fooling around it makes a great local oscillator (add 144 MHz, and mix to get 1296 MHz output).

Construction

Assembly is very easy. You'll need to wind four coils using a 0.1"-diameter drill bit and #24 enameled wire, supplied in the kit. Two BFX89 transistors are used in the oscillator stage, followed by a MAR-3 MMIC, an HP 2835 multiplier diode, a MAR-6 MMIC and another MAR-3 for output. About a dozen chip capacitors are included, and you'll need to use a small pair of needle-nose pliers and a low-wattage iron to solder them in place. Keep all leads as short as possible on the coils and resistors. This isn't hard to do as you can lay each component on top of the board and cut the leads according to the solder pads. I did find some variation from the coil windings in the instructions for the WSS1152, and changed L1 from 10 turns to 11 turns, gaining 3 dB more output and

putting the crystal right on frequency (96.0020 MHz).

A good frequency counter would be helpful to check the crystal and trim it in, but if you have a receiver for any of these bands and you know the calibration, just make a note on the board with permanent marker. If you want to be sure of your frequency, allow the unit to warm up and stabilize for a bit . . . say 10 minutes or so.

Down East offers an option to get a bit more "oomph" from the board by adding another MMIC stage just before the output connector. The parts for this stage (another MAR-3 MMIC, a 220-ohm 1/4-watt resistor, and a 22 μ F chip capacitor) can be ordered at the same time for a slight additional cost. You'll have to wind another eight-turn 0.1" diameter choke from #24 enameled wire as well.

In Use

Down East suggests a Radio Shack 270-238 box for installation. I would prefer to use a small Hammond or Bud die-cast box with a BNC or SMA connector and feed-throughs for

DC power. The board is small enough at 3" x 5" to fit in just about any configuration, and you could put all three together in one box with a power supply and just switch to the desired port. I've used mine to check the sensitivity of several GaAsFET preamps I use on 33 cm, 23 cm and 13 cm. Although the crystal stability would be far better with an oven, drift is pretty minimal after warm up and gives you an easy way to find yourself on any of these bands, especially if you're trying to work another microwave station on a schedule.

Photo A. The Down East Microwave WSS (Weak Signal Source) kits can be ordered for outputs on either 903.1 (WSS903K), 1152 (WSS1152K) or 1296 MHz (WSS1296K).

COMMUNICATIONS SPECIALISTS

The PE-15 from Communications Specialists is a miniature sub-assem-

bly capable of sending 15 separate codes in the POCSAG (RPC-1) format. The PE-15 is intended for operators of local "in-house" radio systems wishing to signal tone-only pagers. It is ideal for factories, restaurants, sales managers, security operations, oil fields, or wherever direct control of local area paging is desired. The 15 available codes may be used to activate up to 4 distinct alert tones on each pager, 15 individual pagers, or any combination thereof. Communications Specialists also makes the PE-4 four-call and PE1000P 1,000 call POCSAG paging encoders. All of these units can be used on most two-way radio systems, providing enhanced capability of existing systems at low cost.

The PE-15 and PE-4 are factory-programmed to your specific address codes, or may be field-programmed via an available keypad. They each sell for \$99.95. For more information, contact *Communications Specialists, Inc.*, 426 West Taft Avenue, Orange CA 92665-4296; (714) 998-3021, (800) 854-0547, Fax: (714) 974-3420. Or circle Reader Service No. 201.

J & W TECHNOLOGY

IRACS (Interactive Remote Alarm and Control System) from J & W Technology is a controller that allows you to perform reliable long-range remote control with your hand-held or mobile radio. IRACS is designed to connect easily to the speaker, microphone and PTT lines of any FM transceiver.

IRACS uses this transceiver to receive DTMF commands from you and to transmit acknowledgements and system status back to your handheld.

Typical uses include remote control and site alarm for your repeater site, home or car. You can use it simply to turn on a remote speaker for selective calling or to turn on a tape recorder remotely.

IRACS is available in the following configurations: fully assembled and tested, with matching case, \$149; fully assembled and tested PC board without case, \$119; complete parts kit with a single-sided PC board, \$99. For more information, contact *J & W Technology*, 38 Jade Street, Scarborough, Ontario, Canada M1T2T8; (416) 298-4499. Or circle Reader Service No. 204.

R & D ENGINEERING SYSTEMS

R & D Engineering is offering two analyzers, the AS-100 and the AS-1750. Both analyzers include power supplies and have the same specifications except that they operate in different bands: The AS-100 operates from 2.8 to 105 MHz, and the AS-1750 operates the 850 to 1750 band. The suggested retail price is \$179 for

the AS-100 and \$259 for the AS-1750, plus shipping and handling. Dealer rates are available. For more information, contact *R & D Engineering Systems*, 502 Canal St., Folsom CA 95630; (916) 985-2555. Or circle Reader Service No. 202.

SAGANT ANTENNA

Arrow Line antennas from SAGANT U.S.A. for HF, VHF, and UHF are compact and lightweight, with a low radiation pattern for outstanding performance. Model AL-207F is a base-type 2m/70cm dual-bander (51" long, 0.77 lbs.) that handles 250W FM. The AL-144F is a compact base antenna for 2 meters. Other Arrow Line models for mobile, 2 meters, HF and 1.2 GHz are available. SAGANT also offers a wide range of wire antennas, such as Zepp-type and inverted V, and HF mobile antennas that are slim and short for mounting on the roof.

For prices and more information, contact *SAGANT U.S.A.*, 360 W. Bedford Ave., Suite 111, Fresno CA 93711; (209) 261-1400, Fax: (209) 261-0662. Or circle Reader Service No. 203.

TIC GENERAL

TIC General has introduced the Model 1022 TIC Ring, downsizing the larger Model 1023 into a compact yet very powerful rotor. Far more than a rotor, this is a Ringrotor, with rugged steel ring construction, a powerful drive motor, solid worm gear braking and galvanized coating. It will mount, hold and turn large antennas. It offers an analog controller, preset, North cen-

ter, South stop, analog meter readout, memory backup, and an easy-to-read scale.

The TIC Ring Model 1022 is \$649 plus S & H. For more information, contact *TIC General, Inc.*, P.O. Box 1, 302 Third Street East, Thief River Falls MN 56701; (218) 681-1119, (800) 842-7464, Fax: (218) 681-8509. Or circle

HAMTRONICS, INC.

The Hamtronics TD-4 Selective Calling Module is a relatively new economy touch-tone decoder with one latching output. This versatile module, only a few inches square, is primarily designed to mute the speaker of a receiver or transceiver until someone calls by sending a four-digit DTMF signal, thus making it unnecessary to listen to all the activity on a channel just so someone can call you

once in awhile. It is easy to modify the latch input circuits on the TD-4 to perform the LITZ function, i.e. mute the receiver until a DTMF zero has been received for six continuous seconds, making it a low cost solution for implementing this new emergency warning scheme.

The TD-4 is only \$49 in kit form or \$89 wired and tested. For more details and a complete catalog, contact *Hamtronics, Inc.*, 65-F Moul Road, Hilton NY 14468-9535; (716) 392-9430, Fax: (716) 392-9420. Or circle Reader Service No. 205.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

Future OSCARs

The first amateur radio satellite, OSCAR-1 (Orbiting Satellite Carrying Amateur Radio), was launched into orbit just over 31 years ago on December 12, 1961. The 10-pound package sent the letters "HI" in code on 2 meters. This small unit was designed and built by members of the Project OSCAR group at Foothills College in Los Altos, California, and the Lockheed Amateur Radio Club in Sunnyvale, California. The 100-milliwatt transmitter system lasted three weeks until the batteries discharged. Over 600 amateurs in 25 countries reported reception of the signals. Since then, many more amateur radio satellites have been launched, and several from other countries are on the way.

Current amateur satellite community attention has been focused on Phase 3-D. Phase 1 OSCARs were designed for short lifetimes and low orbits. Phase 2 spacecraft are built for long lifetime (over one year) operation in low orbits. Phase 3 satellites are placed into high orbits and are usually designed with at least a five-year lifetime. Phase 3-A met a watery end in 1980 when its Ariane launcher malfunctioned. Phase 3-B became AMSAT-OSCAR-10 in 1983 and Phase 3-C was renamed AMSAT-OSCAR-13 when it reached orbit in 1988. Although Phase 3-D will be placed into an orbit similar to the other Phase 3 spacecraft, it is much larger and significantly more complex than its predecessors. Participating groups include the U.S., Germany, Belgium, Hungary, Finland, Czechoslovakia, Great Britain, Japan, South Africa, Australia and Slovenia. The main goals of the project are to improve link margins over previous satellites with more power from the satellite, to promote the use of higher frequencies for satellite communications, and to cut the cost of earth stations and retain sufficient commonality with existing hamsats to avoid obsolescence of current equipment. Launch could be as soon as 1995. Many changes have been made to the structural design of the satellite in recent months, so it will be a challenge to have everything ready in time.

Other satellite projects continue with development and construction or have been proposed for future programs. International satellites are expected soon from Mexico, Italy, Russia, France, South Africa, Israel, Chile and other countries. Here in the U.S., efforts continue on SEDSAT in Huntsville, Alabama, and at PANSAT, the Naval Postgraduate School satellite in Monterey, California.

Some programs from other countries and schools have used amateur frequencies for educational orbiting experiments. These "gray area" projects confuse the issue of what is an OSCAR and have caused serious arguments among international groups. Some have said that the French satellite SARA should be called SARA-OSCAR-23, while others

argue that SARA's operation on ham frequencies was a matter of convenience for the builders. There are also questions about UoSAT-OSCAR-14, which is still operational for commercial and educational uses but not available to amateur radio operators. While interlopers in the amateur bands should be discouraged, AMSAT organizations wish to aid and promote more ham-originated satellite work through checks of the intent of the various groups and their credentials as amateur radio organizations.

Current OSCARs

New hamsats are always exciting. They provide fresh resources for communications and experiments testing ideas from an orbital vantage point. We have seen the results of imaging advances from the early days of UoSAT-OSCAR-9's camera to the dramatic views seen and transmitted by KITSAT-OSCAR-23. Data experiments have gone from CW and RTTY to 9600 bps packet. Voice transponders have progressed from simple Mode "A" systems using the 10 meter band for a downlink to the Mode "S" system on A-O-13 that comes to earth on 2.4 GHz in the 13cm band.

In the early days of OSCAR with Phase 1 satellites, the time between satellite launches was painful since the operational time of the hamsat was usually limited to a few weeks and launch opportunities were rare. Later, with Phase 2 satellites like A-O-6, spacecraft lifetimes of several years were common. Today we have so many amateur radio satellites it is impossible for one person to keep up with them all. Most enthusiasts focus their efforts on the satellite and mode that interests them the most. Newcomers typically try the easy satellites like RS-10 and RS-12 before progressing to the challenges of the high elliptical orbits of the Phase 3 spacecraft.

It's time to take stock of the incredible resources in orbit and available for use in 1993. Rather than wait for the next round of hamsats, or the promised advances of Phase 3-D, it's time to get on the air now. The hamsats are a limited resource. When the batteries finally die, or a key transistor gives out, it's all over.

AMSAT-OSCAR-10 was launched nearly 10 years ago on an Ariane rocket from French Guiana. This satellite still performs very well on Mode "B" using a 70cm uplink and 2 meter downlink. The computer gave in to radiation damage three-and-a-half years after launch, but the transponder system still works well when the solar cells are properly illuminated. The elliptical orbit favors the Southern Hemisphere, providing excellent DX opportunities not available via A-O-13.

UoSAT-OSCAR-11 was launched from the Western Test Range at Vandenberg Air Force Base in Lompoc, California, in 1984. Nine years later it is still performing extremely well with telemetry, bulletins, digital speech and whole-orbit data transmissions. It is usually heard on 145.825 MHz FM sending ASCII data at 1200 bps. Many stations looking for D-

Table 1. AMSAT-OSCAR-13 operation schedule for 1993 from G3RUH.

O-17 find U-O-11 instead since they share the same downlink frequency.

RS-10/11 is nearly six years old. Launched from Plesetsk in June 1987, this dual package is part of the larger COSMOS 1861. Andy Mirinov RS3A has acted as the primary control station from the Command Center of RS Satellites in Moscow. Andy has recently begun work at the Moscow Adventure Club, but continues with the RS control activities. RS-10 remains in excellent condition providing Mode "A" operation (2 meters up and 10 meters down) from its 1,000-km-high polar orbit. The satellite pair can be used in other modes, but "A" is primary. RS-11

is held as a back-up should a failure occur in the RS-10 hardware.

AMSAT-OSCAR-13 was one of the payloads on the June 1988 launch of an Ariane 4 series rocket from French Guiana. A-O-13 continues as the primary voice transponder hamsat. Activity is not limited to a single mode. The current schedule includes the popular Modes "B" and "J" (2 meters up and 70cm down), and also Mode "L," which uses 1.2 GHz as an uplink to a 70cm downlink, and Mode "S."

James Miller G3RUH recently posted a complete preliminary mode schedule for 1993, shown in Table 1. Up-to-date

Table 2. Example of A-O-21 AX.25 AFSK FM data received on 148.983 MHz by N2AAM.

information about A-O-13 operations is always available via the A-O-13 telemetry beacons on 145.812, 435.658 and 2400.646 MHz in CW, RTTY and 400 bps PSK. Active command stations include Peter DB2OS, James G3RUH and Graham VK5AGR. Messages to these volunteers about A-O-13 operations can be sent via the Internet (callsign@amsat.org) or via Compuserve (>INTERNET:callsign@amsat.org). They also get mail via U-O-22. Computer predictions still show a projected reentry of late 1996 for A-O-13.

Several special interest groups can be found on specific frequencies when

the appropriate mode is on, but unlike HF, interference is light. The VHF, UHF and microwave signals are not subject to band conditions. DX chasers can be found on 145.890 MHz almost daily. AMSAT schedules operations nets on 145.950 and 435.970 MHz, and directly afterwards on the same frequencies are SSTV nets.

The MICROSATS, Pacsat-OSCAR-16, DOVE-OSCAR-17, Weber-OSCAR-18 and Lusat-OSCAR 19 were launched on January 22, 1990, on an Ariane 4 rocket from French Guiana with UoSAT-OSCAR-14 and UoSAT-OSCAR-15. U-O-14 is no longer performing amateur

radio service and U-O-15 failed shortly after launch.

The microsats P-O-16 and L-O-19 are currently operational with 1200 bps (potentially capable of 4800 bps) flying mailbox activity. The uplinks are on 2 meters FM with 70cm PSK (phase-shift keying) downlinks. Software changes are uploaded to provide enhanced operation. These satellites also provide terrestrial packet forwarding services.

DOVE-OSCAR-17 is functional but has not spent much time with the popular 2 meter downlink on 145.825 MHz. Efforts by WD0E and others have focused on restarting the 2 meter 1200 bps AX.25 FM telemetry. DOVE stands for Digital Orbiting Voice Encoder and was sponsored by AMSAT Brazil, or BRAMSAT. Since launch, the goal was to send digitized voice messages through the satellite for educational purposes. DOVE has only spoken once and it was with limited fidelity. Those efforts will continue.

Weber-OSCAR-18 continues to take pictures of the earth. This satellite was primarily built by Weber Band University in Ogden, Utah. It is slightly taller than the other microsats since it has a camera "penthouse" on top. Images of Peru, Chile, Northern Australia and the southern tip of India were targets for the winter season. The images are sent to earth at 1200 bps using PSK on 70cm. WEBERWARE software is used to collect the received data and display the results. Students at Weber State have also been studying battery telemetry and other data available from the satellite.

Comparisons of battery data from just after launch to the present will provide valuable information for future microsats.

Fuji-OSCAR-20 was sent to orbit from the Tanegashima Space Center in Japan on February 7, 1990. It replaced the older F-O-12, which lasted about three-and-a-half years. F-O-20 has both a linear Mode "J" transponder (Mode "JA") and a digital mailbox system (Mode "JD") at 1200 bps PSK. The satellite spends most of its time in "JD" but is scheduled for "JA" operation on Wednesdays, UTC. Signals are

strong but careful management of the satellite's power budget and temperature by ground control stations is necessary.

RS-14 went to orbit on January 29, 1991. It is also known as RADIO-M1, RUDAK-2 or AMSAT-OSCAR-21 and is attached to the Soviet INFORMATOR-1. While its linear Mode "B" transponder was very popular at first, today the FM "repeater" mode of the German RUDAK (Regenerative Transponder for Digital Amateur Radio Communications) experiment has sparked the interest of many new satellite chasers. Telemetry and the FM voice (uplink on 435.016 MHz) mode share portions of each 10-minute period. When the system is not acting in the repeater mode, the telemetry can take on many forms, including 1200 bps AX.25 AFSK, 400 bps PSK or even digital voice. Messages of greeting in different languages and even a "get well soon" message sent to Matjaz Vidmar YT3MV have been heard on the RUDAK downlink of 145.983 MHz. Table 2 shows an example of recent AX.25 packet telemetry from RUDAK. The signals were monitored by Dave N2AAM in early December.

RS-12/13 was launched on February 4, 1991, aboard the COSMOS-2123 NAVSAT. COSMOS-2123 is a replacement for COSMOS-1861, which carries RS-10/11. The RS-12/13 package is capable of the same linear transponder modes as RS-10/11, but is most commonly found with RS-12 active in Mode "K," which uses a 15 meter uplink and a 10 meter downlink. Signals are usually strong. Most users call "CQ RS" when accessing the satellite to avoid confusion with other terrestrial 15 meter activity. Many more years of service are expected from RS-12/13, based on the results of RS-10/11.

UoSAT-OSCAR-22 joined the now large group of hamsats on July 17, 1991, primarily as a replacement for the failed U-O-15. After complete commissioning, it has taken over the 9600 bps duties of U-O-14. In addition to serving as a packet mailbox eight times faster than the microsats, it also has a camera experiment on board and has taken some excellent shots of the earth. The 70cm transmitter is not as clean as that of U-O-14 but, with today's modems, copy is very good for the several hundred regular users. Significant amounts of terrestrial packet messages are forwarded through the satellite and its health has been excellent. Messages, programs, pictures and even voice mail have been sent via U-O-22.

Kitsat-OSCAR-23 joined the amateur satellite corps on August 10, 1992. It has a 9600 bps system very similar to U-O-22, but with better transmitter characteristics. The camera system is more sophisticated, with both wide and narrow angle lenses and has provided some fantastic images from space. The mailbox system was released for general use this winter. The orbit is slightly higher than the other University of Surrey-built spacecraft and gives more access time per pass. Some newcomers to satellite packet activity have found the 9600 bps FM mode of the UoSATS and Kitsat less expensive than the 1200 bps PSK mode of the microsats. The link margin advantages of PSK versus FM are overcome by excellent signal levels from the FM satellite transmitters.

JOIN AMSAT

Support the Amateur Space Program

AMSAT Has Established Amateur Radio As a Permanent Resident in Space!

From operating any of 12 Amateur satellites circling the globe today to participating in Amateur Radio activities from the Space Shuttle, the benefits of space based Amateur Radio are available to you by becoming an AMSAT member. Our volunteers design, build and launch state-of-the-art satellites for use by Radio Amateurs the world over. We provide educational programs that teach our young people about space and Amateur Radio. Most of all, we provide our members with an impressive array of member benefits including:

- Operating aides such as discounted tracking software and land line BBS.
- An extensive network of volunteers to provide you local technical assistance.
- The AMSAT Journal, your bi-monthly periodical devoted to the Amateur Space program.

It's Fun! It's Easy! It's Exciting!

JOIN TODAY. For more information, call or write for your free information packet. Or send your dues now, check or charge: \$30 U.S., \$36 Canada/Mexico, \$45 all else. (\$15 towards the AMSAT journal.)

The GAP Voyager DX-IV Vertical

Operate 160 through 20 meters with this high performance antenna.

GAP Antenna Products, Inc.

6010 Bldg. B

N. Old Dixie Highway

Vero Beach FL 32967

Telephone: (407) 778-3728

Price Class: \$390; guy rope, \$39.

For the last two years I've been DXing with 100 watts and two verticals, the Cushcraft R5 and the GAP Challenger DX-VI. The GAP DX-VI is a fine antenna, but its performance on 80 meters is limited by its size and narrow bandwidth. I wanted something better for 80, and also some way to get on 160 meters. Dipoles seemed like a poor choice because of the difficulty in getting them to an effective height. At the 100 watt power level 80 and 160 meters are especially difficult because of the typically higher noise levels and weaker signal strengths, so an effective antenna is a must.

Enter the GAP Voyager DX-IV, the big brother to the GAP DX-VI. The DX-IV is 45 feet tall and covers 160, 80, 40 and 20 meters. The DX-IV was created specifically to provide an antenna solution on 160 and 80 meters; the coverage of 40 and 20 meters is something of a bonus. About 90 kHz is covered on 160 meters, with full coverage on the other bands.

Photo A. The GAP Voyager DX-IV offers 160 through 20 meter operation.

Description

If you're not familiar with GAP verticals, picture a dipole mounted on end. That is the best way I have to describe the GAP DX-IV to you. The feedline attaches to a center insulator (the "GAP") about halfway up the antenna. From there, the feedline comes down inside the lower section of the antenna and exits through the bottom, terminating in a PL-259 connector. Tuning rods attach to three sides of the antenna to provide multiband coverage, and a capacitance top hat (a wire ring six feet in diameter) at the top of the antenna increases the electrical height for 80 and 160 meters.

Unlike traditional verticals, an extensive ground radial system is not required. Only three radials (the manufacturer calls them counterpoise wires) measuring 57 feet are required. The only restrictions on them are that they must be insulated, and they must not run too close to your feedline. They can be buried, and they can zigzag, if necessary, to fit your site. You'll need to provide the wire (it doesn't come with the antenna), but just about any insulated wire will do fine.

I had my DX-IV shipped to my office. It can be shipped by UPS, but you should be prepared to receive a long box. I got some sense of this when the receptionist called and told me, with a note of panic in her voice, that there was an antenna for me in the lobby. She didn't sound too happy. The box is nine feet long, which is the longest allowed by UPS, and weighs about 30 pounds. I managed to get it home in my Taurus by running it diagonally through the car with one end sticking out the front passenger window. If you try this during rush hour, remember to stay on the left side of your lane.

When you unpack the box, you will find several large pieces of tubing, the GAP section with pre-attached coax, and many smaller pieces of tubing. The smaller pieces of tubing are packed inside the larger diameter tubing for protection during shipping. A small box of hardware, the top hat wire, instructions, and a nut driver round out the parts inventory.

Before You Start . . .

Before the antenna can be put up, several things must be done. A suitable site is the first requirement. You'll need a clear area at least 45 feet long with no obstructions (like tree

branches or electrical wires) above it. Four pairs of guy ropes spaced 90 degrees apart support the antenna and attach to the ground 25 feet from the base of the antenna, so the 45-foot figure should really be closer to 70 feet to take this into account. The location of the counterpoise radials should also be considered when selecting a site, although you have more flexibility with their placement. The tuning rods at the bottom of the antenna will be hot with RF during use, so an enclosure should be included if children or pets can enter the area.

Another site consideration is the proximity of other vertical metal objects. Allow at least 70 feet separation from towers, other vertical antennas, aluminum-sided buildings, and so forth. My GAP DX-VI antenna is the closest metal object to the DX-IV, at a distance of just over 70 feet, and it has not caused any problems.

The second requirement is to obtain suitable guy ropes. I assumed this would be easy as I ordered them with the antenna. Unfortunately, the rope was out of stock and had to be back-ordered. With a major contest quickly approaching, I was determined to get the antenna up, so I looked for suitable rope locally. Despite being in a major metropolitan area, I was unable to find a good replacement. The guy rope for the antenna should be rated for 300 pounds load, have good UV resistance, and not stretch under tension. This combination of requirements is almost impossible to find in hardware store rope. I settled on a 240-pound-rated Poly (polypropylene) rope, but I used it knowing that it would need replacement within a season due to its poor resistance to sunlight. The 300-pound load rating will keep the antenna standing in a 80 mph wind, so you can get by with something less for temporary use, like Field Day. You'll need 350 feet of rope in all, cut into eight pieces during assembly for the eight guy ropes.

You can use a variety of ground anchors for the guy ropes. I took a different approach as I didn't want to give up any lawn space to the guy ropes angling down from the antenna. Instead of ground anchors, I placed four 10-foot treated 4x4s in the ground, 25 feet from the base of the antenna, spaced 90 degrees apart. The 4x4s were buried four feet deep and anchored with one bag of ready-mix concrete each. Screw eyes were placed about 5-

1/2 feet up each 4x4 to hold the guy ropes. With this system, the guy ropes don't get in the way when you mow the lawn. More importantly, since the guy ropes are the only thing keeping the antenna up, they are much better protected from accidental damage. I found bite marks recently in the coax that runs to one of my antennas. Unbelievably, the bite penetrated all the way through to the inner conductor of the 9913 (large size) coax. So consider the "critter" factor when deciding how to locate the guy ropes.

The antenna sits on a base mount made of two pieces of angle iron. The bottom of the antenna sits between the base mount and pivots on a bolt. Although the base mount can just be pounded into the ground, I installed mine in concrete. One bag is plenty if you decide to go this route. If you decide to use 4x4s as guy mounts as I did, the base mount should be turned about 10 degrees instead of lining up directly with the 4x4s. Otherwise, one of the 4x4s will be in the way when you try to raise or lower the antenna.

Assembly

Assembling the antenna is quite easy. There is little to measure; most pieces just slide together and connect with screws through pre-drilled holes. The tuning rods are a little less precise. Clamps are used to hold standoff insulators to the main mast, and you must position the clamps. Labels attached to the main mast get you in the ball park. An adjustment step later in the instructions helps

you compensate for any inaccuracy. The instructions are adequate, although the supplied 3-D sketch of the assembled antenna is not very detailed and could be improved.

I had a few problems. A short wire was missing (promptly replaced by GAP). The labels for the standoffs on one mast section were reversed, causing the tuning rods to be out of position. This was caught and easily corrected during the adjustment step previously described. The top hat wire (which comes to you as a closed loop) had a knot in it. I just pulled the knot tight (although this requires pliers because the wire is copper-clad steel). The rods that hold the top hat were difficult to insert through the holes in the main mast (corrected by slightly increasing the size of the holes with a pocket knife).

The most disturbing problem was finding out that the pivot holes at the bottom of the antenna were 90 degrees off their correct position. When you assemble the antenna as it lies on the ground, tuning rods extend away from the top and both sides of the main mast. In this position, the bolt that goes through the pivot holes at the bottom should be parallel to the ground. This way, you can just attach the base of the antenna to the base mount and walk the antenna up. With mine, the antenna would have needed to be rotated 90 degrees, and the tuning rods on the side prevent this.

With some head scratching (and being further motivated by falling snow), I found an easy solution. I unscrewed the base section from the sleeve that connects it to the next section (two screws), rotated it 90 degrees, drilled two new holes in the sleeve, and refastened it. Bingo. Easy fix. I talked to GAP later to review the structural impact of my field modification (no problem), and to find out what had happened. Apparently there was no coordination of holes between the top and the bottom of the base piece, and it usually just worked out OK. They plan to check this better in the future.

Raising the Antenna

With the assembly completed and the site prepared, it was time to raise the antenna. I had three helpers, although you could get by with two—two people should walk the antenna up while the third fastens the guy ropes. Walking the antenna up must be done very slowly. My dad was helping and he was certain that the top of the antenna was going to snap off, but the antenna has been designed to handle this, provided you don't go too fast and let the end whip about. After the antenna is vertical and the first set of guys are attached, you can relax a bit. With both the top and bottom guy ropes attached, the antenna is quite stable and the Individual guy ropes don't seem to be under much tension. We had problems because a few of our guy ropes had been routed the wrong way and made contact with the tuner rods, but we were able to correct this without taking the antenna down by threading the offending guy ropes through the tuner rods with a long pole while standing on a stepladder.

Performance

How does the antenna work? My first two CQs on 160 brought replies from stations about 500 miles away and 589 signal reports. On 80 meters a short time later I worked a 6W in Senegal through a pile-up. During an SSB DX contest, and using just 100 watts, I worked about 10 countries on 80 meters and 30 countries on 40 meters during the contest weekend. My country total on 80 meters has been steadily climbing, and getting through on 40 meters has been a breeze.

Compared to the GAP DX-VI, the Voyager DX-IV not only adds 160 meters capabilities, it provides several S-units of transmit improvement on 80 meters. I often heard stations before on 80 meters while using the DX-VI but they didn't hear me calling them. With the DX-IV, I usually get through. On 40 and 20, both antennas seem close, with the DX-IV getting the edge by a slight margin. Both are great DX antennas for 40 meters. On 20, I usually use the Cushcraft R5, but to be fair, I have it mounted up on the roof of the house where it has a significant height advantage. On the other hand, the GAP antennas are usually much quieter than the R5 (the difference can be like turning on a noise blander, with noise sometimes dropping as much as five S-units), so sometimes the GAP antenna is the only way to go.

The GAP DX-IV met the manufacturers SWR specifications without difficulty. As assembled, I had a usable frequency span on 160 of 1.800 to 1.895 MHz, full band coverage on 80 with 1.7:1 as the highest SWR at the band edges, full band coverage on 40 with 1.6:1 as the highest SWR at the top end of the band, and full band coverage on 20 meters with 1.3:1 as the highest SWR.

Long-term reliability of this antenna should be excellent. Except for a small encapsulated tuning device at the top of the antenna for setting the frequency coverage on 160 meters, everything else is tubing and wire. There's not a whole lot that can go wrong with this antenna, and nothing that couldn't be easily repaired in the field.

Customer Service

Customer service at GAP Antenna Products is excellent. I have talked to several different folks there, and they all were knowledgeable about the product and eager to please. Even though I purchased the DX-IV through their distributor, Amateur Electronic Supply, I received complete support direct from GAP, with no questions asked. It is rare to find a company where the employees have such enthusiasm for their product and treat their customers so well.

Conclusion

If you want a single package providing access to 160 meters, great DX performance on the entire 80 and 40 meter bands, and coverage of 20 meters as a bonus, the GAP Voyager DX-IV is your antenna. Great performance, a rugged design, wide bandwidth and superior customer service add up to an outstanding product.

Using the NE-602 IC in Ham Circuits

The Signetics NE-602 integrated circuit is one of those few devices that strike the imagination because it is well conceived and behaves like it's supposed to. That latter attribute means that it will work well when amateurs design and build circuits without the aid of SPICE tools or an engineering degree. One of the other chips I place in that category is also a Signetics product: the venerable 555 IC timer.

The NE-602N is an active double-balanced mixer (DBM) based on a transistor circuit called a "transconductance cell." It also contains internal power supply regulation and an oscillator transistor. The DBM works to 500 MHz, while the local oscillator

works to 200 MHz.

Figure 1 shows the pinouts of the NE-602 8-pin miniDIP device. Pins 1 and 2 form inputs "A" and "B," respectively. In single-ended circuits, input "A" is typically used, while input "B" is decoupled to ground through $0.05\ \mu\text{F}$ or $0.1\ \mu\text{F}$. In differential or push-pull input circuits, both input "A" and input "B" are used. The push-pull outputs are pins 4 and 5. Again, both single-ended and push-pull configurations are accommodated. The local oscillator transistor base and emitter are brought to the outside world via pins 6 and 7, respectively. The DC power connections are pin no. 3 for signal and DC ground, and pin no. 8 for +V DC. The DC power supply should be less than +7 volts, or regulation provided.

Figure 2 shows the DC power configuration for the NE-602. In this circuit it is assumed that a higher voltage (e.g. +12 volts) is being used, so a voltage regulator is provided to reduce it to a stable +5 VDC. The regulator can be one of those little 78L05 100-mA IC devices because the NE-602 is not exactly a current hog. A 100-ohm series resistor is used to limit current and improve decoupling. At the power terminal of the NE-602 (pin no. 8), there are

Figure 1. Pinouts of the NE-602 miniDIP package.

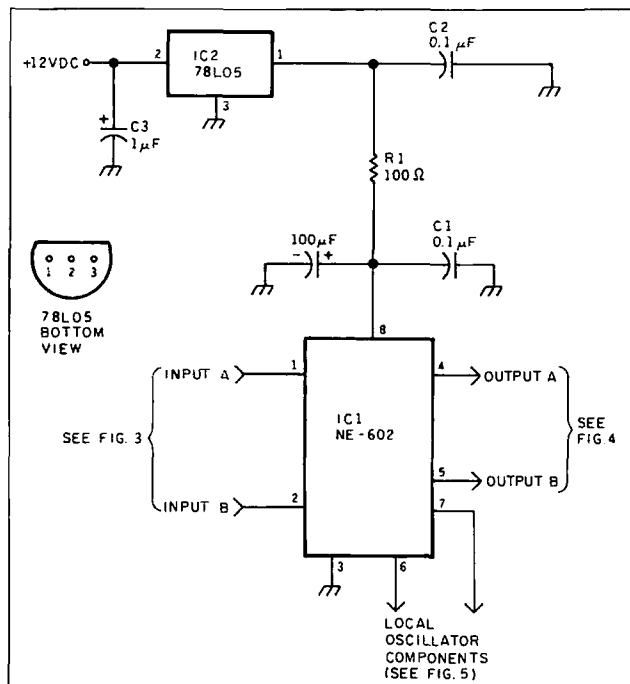

Figure 2. DC power supply circuit for the NE-602.

two decoupling capacitors: a $100\ \mu\text{F}$ unit for low frequencies and a $0.1\ \mu\text{F}$ unit for higher frequencies. I've used just the $0.1\ \mu\text{F}$ unit with no problems, but I note that most articles on the NE-602 tend to include both capacitors.

You can use a +9 volt DC power supply if a 1,000-ohm resistor is used for R1. The goal is to keep pin no. 8's voltage less than +7 VDC when about 15 mA is drawn. Even so, I recommend that the 78L05 device be used instead of depending on a voltage-dropping resistor.

Input Circuits

Figure 3 shows several input configurations. These circuits are quite varied, and which to use depends somewhat on application and somewhat on preference and convenience. For untuned or high impedance applications, use the direct input circuit shown in Figure 3A. This circuit capacitor couples signal to pin no. 1, and decouples pin no. 5 through a capacitor. The signal level applied to pin no. 1 should be less than 200 mV peak-to-peak.

An untuned differential circuit is shown in Figure 3B. This circuit uses an RF transformer that is not tuned for the input signal coupling. I've

used two forms of transformer. First, I've salvaged or adapted, as you prefer, 10.7 MHz IF transformers intended for FM IF amplifier service in transistor radios. The tuning capacitor on the secondary of such transformers can be easily removed in most cases. It is located external to the base of the transformer, in a small recess in the bottom. A small screwdriver or sharp pointed tool will allow access where the capacitor can be crushed into oblivion. The other approach is to wind a toroidal core. I've used the Amidon T-50-2 and T-50-6 cores in 75/80, 40 and 20 meter NE-602 receiver applications with good success. Each core was wound with about 20 turns of #26 AWG enameled wire on the secondary, and about four turns of the same wire on the primary.

The same sort of transformer can be used for the tuned variant shown in Figure 3C. In this particular instance the tuning capacitor floats across the secondary of the transformer. This method works when the capacitor is a trimmer type, or can be insulated from ground. But most variable tuning capacitors are designed to be grounded when mounted to the chassis, so a circuit similar to Figure 3D must be used. In this case, the

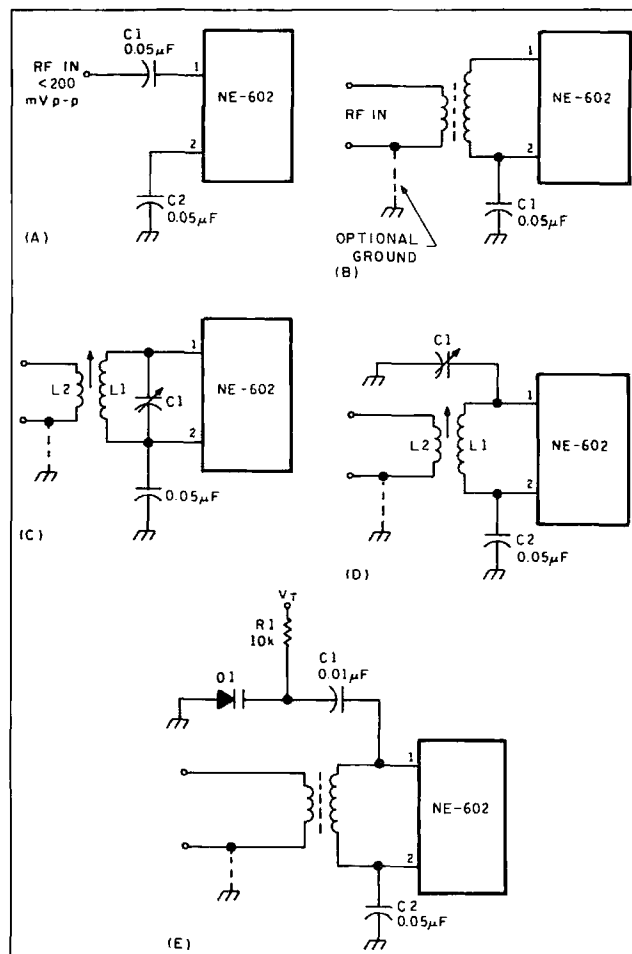

Figure 3. Input circuits for the NE-602.

tuning capacitor is connected from pin no. 1 of the NE-602 to ground. As long as C2 has a value that is considerably larger than the value of C1, the circuit will tune very much like that of Figure 3C.

Finally, given that air dielectric capacitors are hard to find, and often quite costly when available, a varactor-tuned variant is shown in Figure 3E. This circuit uses a voltage-variable capacitance diode to tune the transformer. A tuning voltage Vt from a potentiometer will set the resonant frequency of the circuit.

Output Circuits

Figure 4 shows typical output circuits. Again, several variations are shown. In Figure 4A, the untuned single-ended output circuit is shown. This circuit capacitor couples the signal from either pin no. 4 or pin no. 5 (it rarely makes any difference which) to the rest of the circuit. A balanced output transformer version is shown in Figure 4B. This circuit can use an ordinary IF transformer that matches the 1,500-ohm output impedance, or be specially wound for other applications. A single-ended tuned circuit is shown in Figure 4C. This circuit uses a parallel-tuned resonant tank circuit connected with one end to either pin no. 4 or pin no. 5 of the NE-602, and the other end to V+. Although the output signal is taken from a link winding (L2) on the tuning inductor (L1), it is also possible to capacitor-couple the output with the tank circuit in place. In either event, the output frequency selected will be that of the resonant tank circuit.

"The NE-602 is one of those well-designed little chips that has a lot of amateur radio uses."

In most modern receivers a ceramic, crystal or mechanical filter is used for the IF resonator. Connection of these types of filters is shown in Figure 4D. Resistors R1 and R2 are set to match the impedance of the filter.

The internal local oscillator can be used in either VFO or XTAL configurations. Figure 5 shows several variations on the theme. The circuit in Figure 5A is a crystal-controlled Colpitts oscillator. The two capacitors are semi-critical. The values of these capacitors should be on the order of:

$$C1 = \frac{100}{\sqrt{F_{\text{MHz}}}} \text{ pF} \quad [1]$$

and,

$$C2 = \frac{1,000}{F_{\text{MHz}}} \text{ pF} \quad [2]$$

Although these equations give the impression of a fair degree of precision in the matter of capacitor val-

ues, I've found that they are only semicritical. In one NE-602 oscillator that I built I found that changing the crystal frequency more than an octave (i.e. 2:1) did not overly disturb the operation. Those capacitors should be some sort of low tempco type, however, such as polystyrene, silvered mica or NPO ceramic (these same capacitors can be used for any of the oscillators shown here).

The rest of the circuits in Figure 5 are variable frequency oscillators (VFOs). The circuit of Figure 5B is a parallel resonant Colpitts design. Note that the parallel resonant tank

circuit (L1/C1) is tied on the "cold" end to either V+ or ground (and it doesn't seem to matter which). The other capacitors in the circuit are selected similarly to those of the crystal oscillator, except that C2 is a 0.01 μF unit.

A Hartley variant is shown in Figure 5C. This circuit uses a tapped inductor for feedback. The capacitors in the circuit (C2 and C3) are 0.05 μF disk ceramic or polystyrene devices. The tuning capacitor is an air variable with a grounded frame.

Another VFO circuit is shown in Figure 5D. This circuit has worked well from 80 meters up through 20 meters. It is based on the use of a varactor ("voltage variable capacitance diode") capacitor. The capacitance of this diode is set by the level of tuning voltage Vt applied to the reverse biased junction of D1.

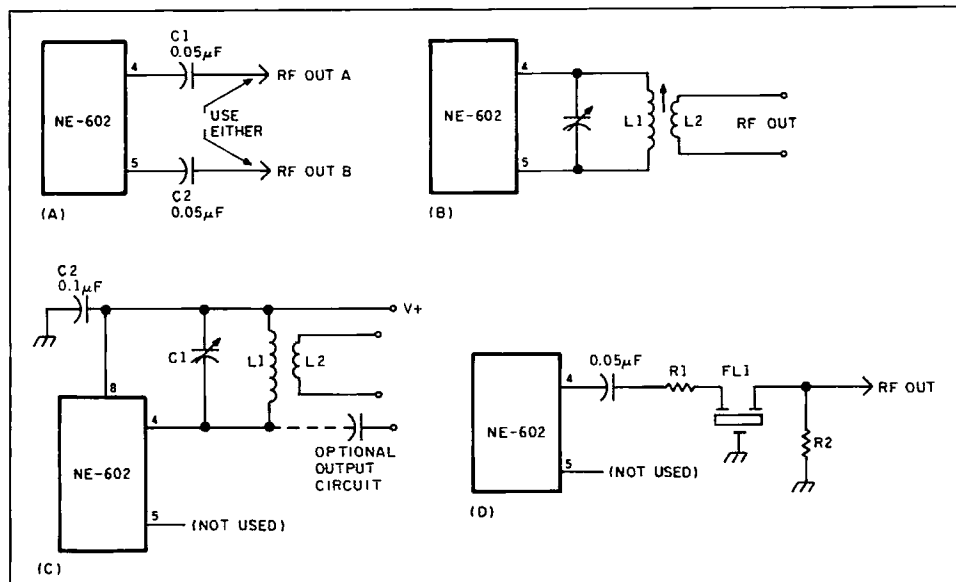

Figure 4. Output circuits for the NE-602.

The NE-602 is one of those well-designed little chips that has a lot of amateur radio uses. Space does not allow us to go further in depth on the device. I am currently writing a book for TAB called *Mastering RF Circuits* (the actual published title may be a little different, but the "Mastering" part will remain because it is part of

a series). It will deal in depth with the NE-602 and certain related chips. In the meantime, I would be interested in hearing from readers who have used the chip. Please relate your experiences and any novel uses for it. You might see your name in print if the application is interesting to a broad spectrum of readers.

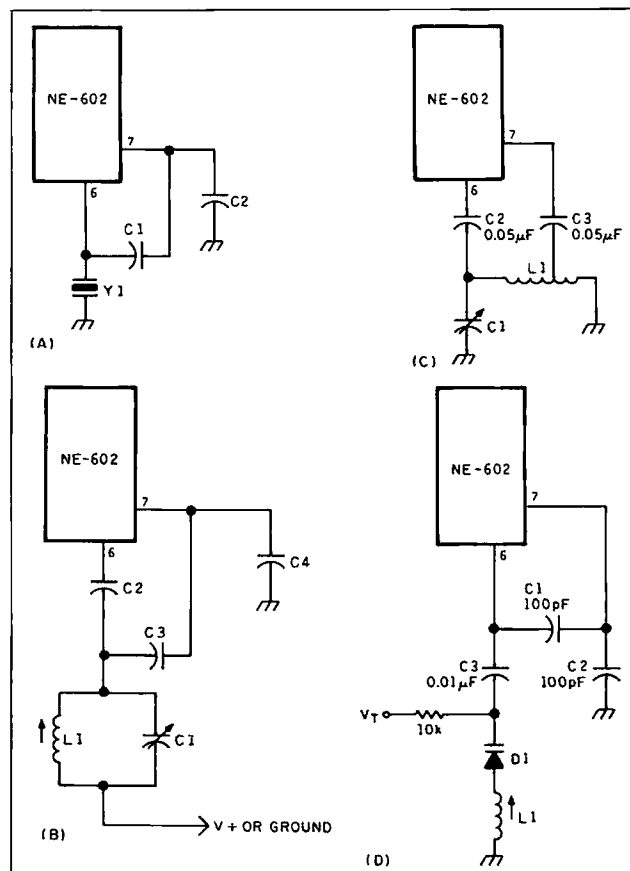

Figure 5. Local oscillator circuits for the NE-602.

Radio Direction Finding

Joe Moell, P.E., K0OV
P.O. Box 2508
Fullerton CA 92633

A Computer on Your Team

Part of the attraction of ham radio as a hobby is the opportunity to use new gadgets to communicate. Hams were among the first to embrace the personal computer as a tool. PCs send and receive CW, RTTY, packet, AMTOR, and SSTV. They log contests, design antennas, and predict band openings. And now resourceful hams are using them to help win radio direction finding (RDF) contests, sometimes called foxhunts or T-hunts.

Last month you saw how Albuquerque T-hunter Jerry Boyd WB8WFK uses a continuously-turning potentiometer at the bottom of his mobile antenna mast to drive a "heads up" direction display on the dashboard (Photo A). The azimuth reading, S-meter voltage and some other signals go to an interface box for digitizing. A laptop computer crunches the data and displays a polar plot of amplitude versus direction on the computer screen. The polar display makes it easier to sort through multipath and noise to find the best bearing to the hidden T.

Although this isn't a project for beginners, WB8WFK's design is straightforward. Hams with a moderate amount of experience with analog and digital circuits can readily reproduce it or adapt it to their own T-hunting needs. This month, we'll examine Jerry's design in greater detail.

Bearings Into Bytes

Figure 1 is the schematic for the analog-to-digital (A/D) circuitry. Each of the eight analog inputs (three are unused at present) passes through an RC filter (R1-8/C1-8) to remove high frequency noise. The filters are on a small circuit board near the BNC analog input connectors.

Filter outputs (even-numbered pins of J2) go via ribbon cable to the main board and into U5, a CD4067 analog multiplexer (MUX). Odd-numbered pins are grounded to minimize noise pickup. Inputs D0 through D2 select the channel address. Only eight of the 16 inputs on the CD4067 are used.

U4 is a National Semiconductor ADC0801 8-bit A/D converter. R3, R4, D1, and D2 provide input protection. Input/output connections to the microcontroller board are made through P1.

U1 and U2 perform address decoding. The A/D is placed at microcon-

Photo A. Jerry Boyd WB8WFK is ready to go T-hunting with his yagi connected to a digital bearing display system. His analog display and interface box are on the dashboard.

troller address \$8000 hex. Since only address lines A12-A15 are decoded, the ADC0801 responds to addresses from \$8000 to \$8FFF. The A/D is the

only hardware in this I/O address space. To start a conversion, the microcontroller program writes to address \$8000, then reads from the

Portable Power/Charger Only \$ 79.95*

- Multi Output at 3, 6, 9 or 12VDC
- Charge from AC or 12vdc source
- Automatic shutoff at full charge (12v recharge less than 3 hrs)
- Built-in Voltage - Charge Meter
- Sealed lead acid 6.5 AH battery
- Supplied with 12 VDC cigarette plug and UL listed AC adapter
- Weight: 8 lbs, LWH 7" x 4" x 8"
- Great power for Field Day, Contests, Mobile, HTs, TV, RV, cellular, camcorder, 12v vehicle/boat starter, and all of your indoor/outdoor portable power needs!

Window Mount BMW-1 Only \$ 13.95*

Get your rubber duck outside with the BMW-1 Window Mount. This handy mount clips over your car's window and lets your antenna get out and above the car roof giving you better range into your local or distant repeater. High quality BNC to BNC connector can be used on your own coax or with optional 6'

50 ohm, Model BC 6-174 Cable, priced at only \$ 10.95* You can buy both the mount and the 6' cable for \$ 23.00* (cable and antenna shown in photo are extra cost options)

LOGIC 3's packet cluster interface

LOGIC 3's packet cluster interface spots not only unconfirmed DXCC countries but also CQ zones, ITU zones, prefixes, continents, and anything else that can be determined from the call-sign (oblasts, provinces, etc.). Audible CW alert for each award type. LOGIC 3's data window is also perfect for RTTY, AMTOR, and CW operation. The flexibility, ease of use, complete logging, awards tracking, and contesting, QSL route facility, and rig control which made LOGIC 2 so popular are now enhanced by windowed screens with full mouse support and graphical report layout (MS Windowstm not required). Superb documentation and tech support. LOGIC 3 (\$79) and LOGIC Jr v3 (\$39) for IBM 386SX or higher. LOGIC 2 & Jr v2 still available on Amiga and ST. Soon for Mac. Hard drive required. Free Intopak. Visa/mc.

Personal Database Applications, Dept 7, 2616 Meadow Ridge Dr, Duluth, GA 30136-6037. tel 404-242-0887 fax 404-449-6687 tech 404-417-1899

same address to get the data.

The A/D's INTR line is connected to memory-mapped port B7. The microcontroller can read this bit to determine if data is ready after a start command. This is not necessary with BASIC programs, but would be needed if a machine code program is used in the future. Jumper JK2 is included to disable this function. Jumper JK1 allows a test voltage from R2 (read at TP1) to be fed to the A/D.

Jerry uses a Micromint model BCC11 computer/controller, which contains a Z8 CPU. It also has a Tiny BASIC interpreter, 6K bytes of RAM and EPROM, one RS232 port, and two parallel ports. It costs \$139 and is available from Micromint, 4 Park Street, Vernon CT 06066; (203) 871-6170. If you don't want to build your own MUX-A/D circuit, Micromint sells an 8-bit 8-channel MUX-A/D board for \$129.

The Z8 board requires 5 volts at 250 mA for the logic and +/-12 volts at 30 mA for the RS-232 port. You'll need a regulator to supply 5 volts to the microcontroller and A/D board. Small DC-to-DC converters are available to supply -12 volts.

The digital circuitry could produce RFI on 2 meters. WB8WFK had no problems on his local hunt frequency (146.565 MHz), but has "birdies" elsewhere on the band. If this bothers you, check to see if the problem comes from the laptop or the A/D box. Try EMI filters on the power supply and

analog inputs. Use good shielded cable for the RS232 link. Powering the system from a battery separate from the vehicle may also help.

Upon starting the program, the PC downloads the Z8 control program from disk to the BCC11 via the RS-232 port at 4800 bits per second. Then it sends a run command to start the BCC11 and displays the main menu.

Jerry prefers the Tiny BASIC method of Z8 programming. "You could burn the program into the on-board 2732 EPROMs," he says. "That would allow faster link speed. But it's nicer doing it my way. On the first hunt, I found something I needed to change. So I typed in a mod to the program file on the PC and reloaded it on the fly."

"You can use any microcontroller instead of the BCC11," he continues, "as long as the software looks like the host mode of a TNC. My PC software sends a command, the Z8 interprets

the command and sends back the data in the format that the PC wants. It would be easy to rewrite the PC software to go with another microcontroller because command definition is simple. For instance, when you go into data acquisition, my software sends a '3' to the controller and it sends back the data packet. There are similar commands for the other modes.

"One thing to watch out for is that the PC software needs a routine to

flush out stuff that's echoed from the microcontroller. For example, the BCC11 echoes the command, carriage return, line feed, a question mark and a space. My software strips that stuff out."

Crunching the Data

A computer with 386 CPU is best for the display because of its high speed. WB8WFK and KA8JMW have experimented with an inexpensive Ky-

Photo B. Inexpensive laptops such as the Model 100 clone can display bearings. The screen resolution is good enough for an X-Y plot of signal strength versus azimuth, but not a polar plot.

ATV in Monterey, California

When your ATV group pools resources and equipment, the ability to support public events with an impressive display of visual communications becomes possible.

This month I'd like to feature one such group from Monterey, California. The Monterey portable public service ATV group was started by Doug McKinney KC3RL in 1987. Prior to that time, ATV was primarily a base station activity. Doug came to Monterey from Washington, D.C., where he had developed expertise in portable ATV public service events through the Metrovision ATV Club (featured in Chapter 16 of the *ARRL Operating Manual*).

The following is a description of the Monterey group's recent activities as described by Doug McKinney KC3RL:

Portable Public Service ATV

In 1987, a group comprised of Doug KC3RL, Elliot KB3LY and Don KB6BZL began to use portable ATV equipment at small 5K runs. These small events generated enthusiasm. Within two years, the ATV group had grown to six ATVers supported by extra equipment loaned by the original group of three. Having a supply of extra portable ATV transmitters, antennas, downconverters, coax and masts really helps when covering these public events. One of the benefits is that you have someone else at the other end to receive your picture!

Today we have nine ATV operators with equipment and 11 trained operators without ATV equipment. In addition, we have coordinated with the South Bay Amateur Television Club members to help with events (in particular Don KK6MX and Renie KC6NBS). The Santa Clara Red Cross ATV coordinator, Bob KB6FEC, has been very helpful by loaning us ATV equipment. Bob's equipment loans have also helped a brand-new group in Alameda County, spearheaded by a dynamo ATV public service coordinator, Sue KC6WXXO.

Our public service group has two main purposes: audio and visual communications to help assure public health and safety, and to give operators experience that would enable them to be prepared to assist in the case of a disaster. There are two major events that our group covers that are significantly different in complexity and require what we call the *serial* and *parallel* mode for public service support.

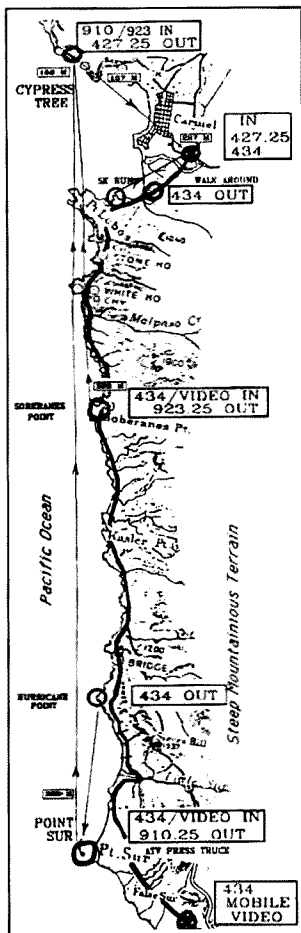

Figure 1. System diagram of the Base Station Control Center for the Hot Air Affair balloon festival.

The Hot Air Affair

The Hot Air Affair is a three-day hot air balloon event held in February at the Laguna Seca Recreation Area and Raceway in Monterey. Laguna Seca is a crater-shaped valley that is 200 feet below the encircling foothill ridge line. This event requires us to use a *parallel* reception path (all transmitters sending to one control site).

In this event we transmit video from the ridge lines into Laguna Seca so the event leaders can see outside of the crater to monitor the sunrise and where the fog is (or isn't). This ensures appropriate start times for safe launches. Once the balloons are launched the event leaders are able to monitor where *all* of the balloons are going and direct chase crews for recovery. Additionally, the event leaders wanted ATV from one of the balloons, providing a unique observation platform for spotting any unexpected

Photo A. Don KC6BZL transmits a bird's-eye view of the hot air balloons back to the launching area from his location on the ridge overlooking the Laguna Seca Recreation Area.

Photo B. Reception from the remote transmission sites is displayed on monitors in the control tent at the hot air balloon launch point. (l to r): Ron KM6DZ, Elliot KB3LY and KC WA6TMK.

problems.

The Hot Air Affair has been 100% successful for the last four years due primarily to performing field tests prior to the event to ensure P5 performance from each site.

The Big Sur International Marathon

This is a one-day event held in April. The runners start at Big Sur and run 26 miles to the north, ending up in Carmel Valley. It's a 26-mile "straight line" run on Pacific Coast Highway 1. If you have ever been on Hwy. 1, you know it's anything but straight! The Pacific Ocean is on one side and a very steep mountain range (2000+ feet) is on the other. This rugged 26-mile section isn't accessible by either

fixed ham repeaters or cellular phones. The *ONLY* communications available for this event are portable ham radio remote bases (2m, 220 and 440) and portable ATV repeaters! The nature of this terrain requires us to use what we call the *serial* mode of ATV transmission (signal A going through repeater B and repeater C to arrive at station D).

Each remote ATV site is completely isolated from outside help. As a result, what you have with you is all that you will have during the event.

We have never been completely successful in getting a picture to the finish line throughout the duration of the Marathon. Any number of factors can result in failure in a serial system

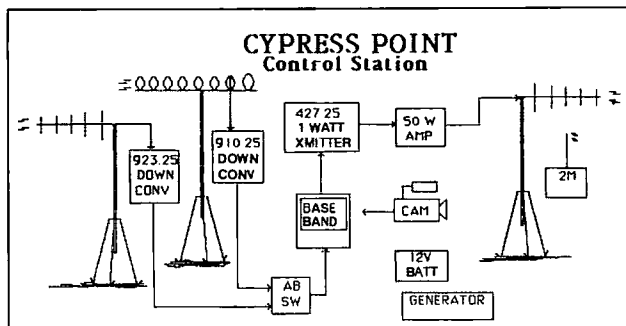

Figure 2. The system used for the 26-mile Big Sur Marathon includes several crossband repeaters at strategic locations along the rugged Pacific Coast Highway 1.

(if just one site goes down, the whole system is out of the picture). In pre-Marathon testing everything worked well, but problems developed during the actual event.

We've listed some of the things we now watch out for (gathered from the School of Hard Knocks) during testing of this kind of system that may be useful for those planning such an event:

- Check all of the equipment and operators in the pre-test.

- Use good coax and standardized connectors.

- Have the ability to do on-site repairs (butane soldering irons come in handy on top of a remote hill).

- Use a power source with proper connectors and an ATV transmitter

PORTABLE ATVERS IN MONTEREY

Ron KM6DZ	Rick K6TST
Renei KD6OCP	Charles KC6UXP
Barbara KC6AWM	

adjusted for operation on 12.5-volt battery power (instead of the normal 13.8 volt shack power). The pedestal adjustment on our 910 MHz ATV transmitter seemed particularly sensitive to voltage changes.

- Have a portable TV at each site to monitor your signal (LCD sets work great for this) to verify that your transmitted signal is good.

- Reduce interference by using high-gain antennas before resorting to increasing transmitter power.

- Cross polarize antennas for multiple inband transmitters (about 20 dB or about two P-units reduction in interference is possible).

- For crossband repeaters, use a portable 5" color TV which has video in and out capability (i.e. downconverter into channel 2/3 and baseband video out to the transmitter). This arrangement lets you see the video quality of the received signal.

- Use interdigital (VSB) filters to reduce inband and crossband interference.

Planning for Success

Good planning is absolutely required for success. If your group would like to cover an event, here's some basic elements you should investigate before you start:

- Determine the public service need.
- Develop a detailed plan with the

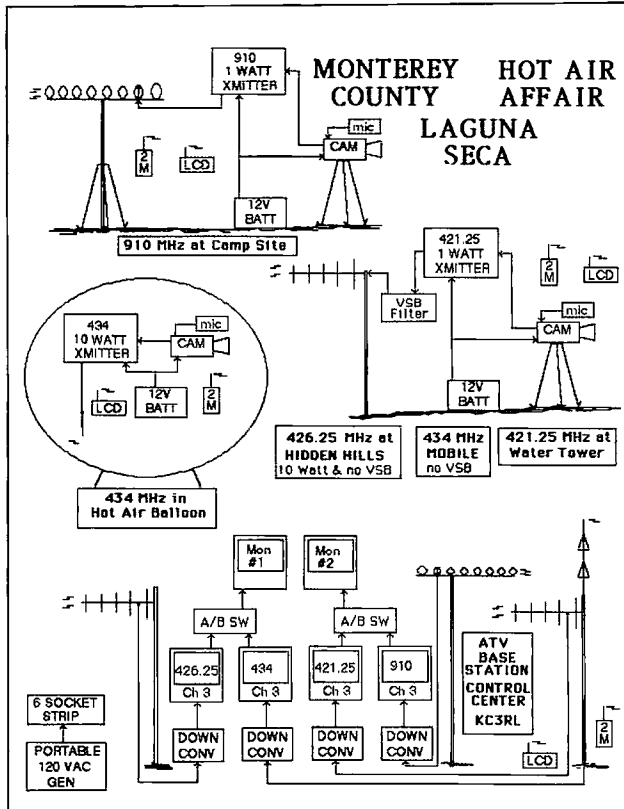

Figure 3. The Cypress Point relay and control station has two 900 MHz band inputs which can be selectively repeated out on 427.25 MHz.

resources available.

- Coordinate with the event leaders to ensure that their needs are met.

- Test the full plan well before the event (see the previous section for problem areas you may encounter).

- Since our early efforts, we have found our limitations and we have found new solutions. Coverage of these events is a great way to get the local ham population involved in ATV and public service. By following these simple guidelines, our group has be-

come proficient in point-to-point and remote base repeater ATV operations.

There is another benefit to our experience in covering public events. In the event of a disaster, our group is ready to provide portable video capability for emergency relief efforts wherever needed. To this end we periodically participate in disaster preparedness drills. It's always great to impress the ARES coordinators with P5 video at the command center during a disaster drill.

Photo C. Bev KC6AMI operates mobile ATV from the press truck during the Big Sur Marathon. Note the small LCD TV she uses to monitor her transmissions.

Discovering The Discovery Place

When Ervin Jackson N4BIG and Tom Bradbury NU4G first began telling me about their exciting efforts at Discovery Place in Charlotte, North Carolina, I knew that there would be lots of great ideas worth sharing with other teachers and instructors. The Mecklenburg Amateur Radio Society envisioned a place where thousands of visitors, especially youngsters, could be attracted to an exhibit that would educate them in ham radio, electronics, and world geography.

Over 500,000 people a year come to visit the South's largest science and technology museum, and its mammoth new Kelly Space Voyager Planetarium and Charlotte Observer Omnimax Theater. Discovery Place, now the W4FB Amateur Radio Education Center, is part of the museum's new \$14 million Michael J. Smith Wing, which opened last fall. It was named for the North Carolina astronaut who was killed in the horrific space shuttle *Challenger* explosion.

Ervin tells me that the very newest attraction is the addition of TV. This attraction has really excited the student visitors (over 100,000 schoolchildren each year) because they can easily identify with TV. The television input frequency is 439.25 and output is 421.25. If you are a home viewer in the Charlotte area, you can tune into cable channel 60 for the input picture and cable channel 57 for the output picture. The audio input is on 2 meters at 147.45 and the output audio rides on the subcarrier

of the TV channel. The TV repeater is W4PHN.

Both Ervin and Tom speak enthusiastically about how popular Discovery Place is once the school year begins. All the science classes of the Mecklenburg School System attend Discovery Place for lectures that are considered part of their regular curriculum. Until 2:30 p.m. each day one can see school buses coming and going; then there is a lull until the after-school crowd arrives. It seems that everyone goes by the station at least once during a visit to the "hands on" museum.

The station sits behind sliding glass doors between the museum cafeteria and the gift shop, just down the hall from the Omnimax entrance. Station manager Bob Southworth K14YV is a retired electrical engineer who, by all accounts, has a world of patience with the youngsters who line up for on-the-air demonstrations. Two ham radio volunteers are needed to handle the large crowds that come through the exhibit—one of them keeps the QSOs going while the other answers specific questions from the students and visitors. Those who visit the station can see demonstrations of the hobby with a packet station, an all-mode 2 meter rig and an HF setup, complete with a beam atop a 60-foot tower mounted on the roof of the five-story museum addition. There is even an SWL corner where they can tune the shortwave broadcast bands.

The station also has groups who visit with prearranged appointments. These groups are given a 20-minute lecture about amateur radio. Live demonstrations follow, and then a question-and-answer period. Ervin also informs me that they have enjoyed the visits of

many foreign hams who have talked with the station previously and wanted to see it. Wonderful contacts have developed between other science museum stations, notably Montreal, Canada, and London, England.

Guidelines for a Ham Radio Exhibit

The group has put together an excellent list of suggestions for anyone interested in assembling a ham radio exhibit. I'll list some of the key suggestions, along with a reminder that these ex-

hibits are excellent projects not limited to museums—they can do wonders for your recruiting efforts when properly set up in a mall, at a school, at a convention center, in a church, at a scouting meeting, at a local fair, or anywhere large groups of people, especially youngsters, will be attending.

1. Display of QSL cards from all over the world. This has a high visual impact and conveys the message that we talk to the world. Be sure to include an insert explaining what the informa-

tion on the card means, i.e. RST means readability, signal strength, tone.

2. Frequency spectrum chart. Like the QSL cards, this is visually attractive and requires no personnel. It can show where the ham frequencies are located with respect to radio, TV, police, and fire, etc.

3. Chart showing requirements for a ham license. List the license categories, with a brief description of the requirements for and privileges of each.

4. Handouts. Hand out the many attractive ARRL brochures, along with an ARRL coupon to mail in for more information. Distribute a sheet listing club meetings for all local radio clubs and a list of where the Novice classes are held. A handout with the Morse code and Q signals on it is always a favorite.

5. Comparison chart showing the differences between CB and ham radio. Folks are particularly interested in noting the power and frequency differences. I do this with my own ham radio classes every year, and the children can relate to it since most of them are already familiar with CB.

6. Photo collage showing ham radio activities. Be sure to have lots of pictures of children having fun in various ham radio activities. Include Field Day, hamfests, emergency communications, local parades, satellites, contests, repeaters, traffic handling, antenna installations, etc.

The club also suggests having two booths with a key and buzzer in each, along with a copy of the Morse code, a

ham-band-only receiver behind a protective plastic shield, but extended tuning knob, volume knob, and band switch through the plastic, along with earphones to hear ham radio QSOs.

Other good ideas for the exhibit include: a price list showing station costs, starting with a very modest setup—debunk the notion that it is a very expensive hobby; a world map showing call letter prefixes; a Morse code decoder box to decode received CW signals, or a continuous tape to feed the decoder box at about 5 wpm, and a set of earphones; a small terminal to monitor packet radio activity on 145.01; and an exhibit of old radio gear and new radio gear as a contrast.

Through the outstanding efforts of groups like the ham radio operators who support and maintain the station at the Discovery Place, and other such museum groups throughout the country, hundreds of thousands of children and adults are being exposed to the excitement and diversity of amateur radio. These museum groups are to be commended for their achievements. We as educators and instructors should support their good works and take advantage of what is being offered by bringing classes to these exhibits and by publicizing what they're doing.

For information on operating hours for Discovery Place and the W4FB Amateur Radio Education Center, write to: Discovery Place, 301 N. Tryon Street, Charlotte NC 28202; or call (704) 372-6261.

Power MOSFETs

The schematic shown in Figure 1 shows how a power MOSFET is configured as a high-side switch. Also, note the difference between the "P" channel device and an "N" channel device. The use of a "P" channel power MOSFET allows the designer to cut the number of discrete components because a charge pump circuit will not be required. On the other hand, the use of a "P" channel power MOSFET,

with its higher $R_{DS(on)}$, will generate more heat and thus diminish operating efficiency. It then becomes a trade-off in the number of extra parts needed for the gate driver (voltage pump) or the loss of efficiency with the "P" channel device. Even the best "P" channel power MOSFET on the market has a rather high $R_{DS(on)}$ of an ohm or two.

You can use the power MOSFET as a simple switch. I have used them to replace a switching transistor in some projects. A common example is to use a transistor switch to operate a relay for T/R control. As shown in Figure 2, a power MOSFET will work

Figure 3. Using a transistor switch to supply the gate drive.

quite nicely in this configuration. The only requirements will be the proper gate voltage and, of course, the amount of current the relay will draw. This is normally not a problem with a power MOSFET; a drain current of several amps is common.

The power MOSFET is turned on by applying +10 volts to the gate. This requirement is easily handled by using a CMOS gate since the output of the CMOS gate is usually over 10 volts when operating with a 12-volt VCC line. Depending on the MOSFET, gate capacitance may cause some distortion when rapidly switching the MOSFET. In the case of our T/R relay, the distortion will never be noticed. Capacitance of several pF to several thousand pF is common, depending on die size. In some cases, paralleling CMOS gates together will help overcome the difficulty in driving the power MOSFET directly from a CMOS IC.

With the extra gate capacitance, the turn-off time may be too long. A transistor switch may be added to reduce the on time after the gate drive has been removed.

Using TTL logic will increase the drive current, but the normal VCC of TTL logic, just +5 volts, will not drive

the power MOSFET fully on. In this case, a transistor switch may be employed to supply the gate drive. Such a circuit is shown in Figure 3. Notice the use of a PNP transistor. When the base of the transistor is pulled low, the transistor is turned on and voltage appears on the collector. This voltage then turns on the power MOSFET. Again, this circuit will work up to several kHz before the switching distortion becomes troublesome.

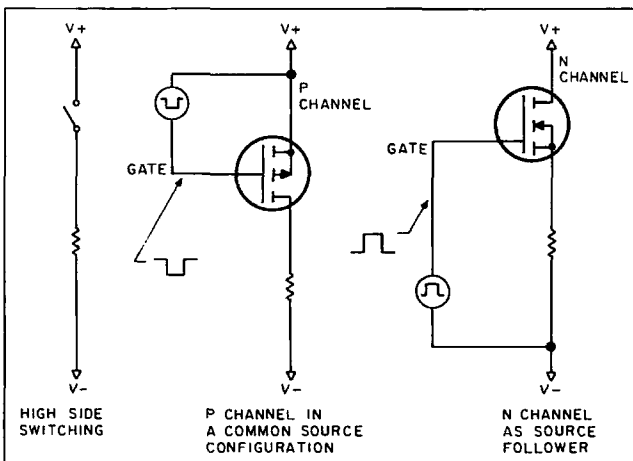

Figure 1. The power MOSFET configured as a high-side switch.

Figure 2. Using a power MOSFET to operate a relay for T/R control.

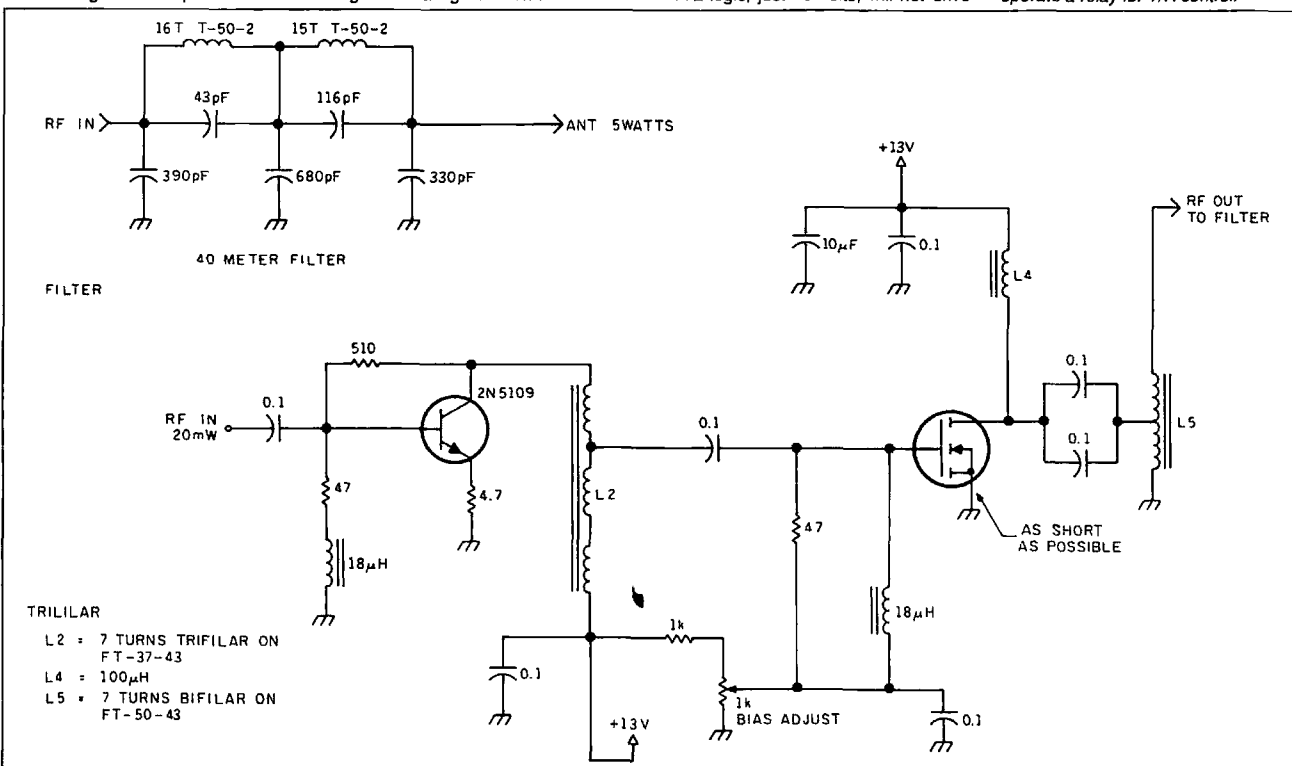

Figure 4. An RF amplifier using a single transistor and a power MOSFET.

RF Amplifier Circuit

Only now are we seeing designs using power MOSFETs in RF applications. Figure 4 is a simple RF amplifier using a single transistor and a power MOSFET. I did not design the circuit—credit for it goes to Bruce Franklin KG7CR. The circuit originally came from the Northwest QRP club newsletter, June 1992. Bruce kindly gave me permission to present it here to you. I have not had the time to build the circuit myself, therefore I can't comment on its performance. Bruce says the circuit will produce 5 watts of RF with only 20 milliwatts of drive. Bruce's original schematic contained some fancy band-switching features using reed relays and a 4015 IC. This schematic shows only the driver and the MOSFET PA components, along with one section of the output filters. The output filter values are for the 40 meter band.

You can use the amplifier for SSB, too! All you have to do is set the bias to about 50 mA with no drive. If you're a CW-only person, then a much lower bias will do. Bias is set by R5, the 1k trimmer.

Suitable sources of RF drive may be VFO, VXO or even the output of a mixer such as the NE602. In the case of the VFO, an extra stage of buffering may be needed if you notice pulling of the VFO frequency.

Also notice that the VCC for the amplifier is only +12 volts. It would be

possible to get better efficiency at a higher voltage, but then you would need to re-compute the values of the LC networks. Of course, you would have to split the circuit in half as the +28 volts would be too much for the bipolar transistor used as a driver.

Bruce uses the IRF510. The IRF511 is available from Radio Shack for under \$2. If you can't find it, an IRF531 would be a good substitute to try.

A very good application of a power MOSFET used as an RF amplifier is described in the November 1990 issue of *73 Amateur Radio Today*, page 36: "The MOuSe-FeET," by Bill Heishman N5HNN. I had the good fortune to work on this amplifier and can say that it works first-class all the way.

As shown in the original article, the filter values are for the 40 meter band. The values for the 20 meter band are as follows:

L1	6T x 1/2
L2	3T x 1/4
L3	9T x 1/2
L8	6.8 µH
C1	1000 pF
C2	Not used
C3	1360 pF (2 x 680 pF or 2 x 500 + 270 pF)
C4	250 pF

All coils are 20-gauge copper magnet wire air wound on 3/8" form and spread to proper length.

With my HW-8 on 40 meters and running both the amplifier and the

HW-8 on a 12.6 volt supply, I had 20+ watts (my QRP wattmeter only goes to 20 watts and the needle was pegged) going into the dummy load. I know had I increased the supply voltage to 13.8 volts, my output power would have been close to 30+ watts. The heat sink became rather warm with the 20 watts and more than likely a larger hunk of aluminum is necessary at higher power. My aluminum heat sink measured the same size as the PC board and was 1/8" thick. The relay-less QSK keying is a real pleasure to use, too. If someone really wanted to, a band-switching model could be constructed to give multiband performance. Operation on 10 meters may result in slightly lower output as noted in the original text. Circuit boards for the amplifier are available from Far Circuits, 18N640 Field Court, Dundee IL 60118.

Toroids and the Wattmeter

Several months ago when discussing the directional wattmeter, I mentioned the cores used as being "special." That's true and I still

don't know what kind of material is used for the core. I mentioned I'd try a T-50-6 core as a start. Several readers wrote to tell me that's the wrong type of material for use in this type of project. I mentioned the T-50-6 core primarily because the ones used in the project are yellow, just as a T-50-6 core is. Hold up a T-50-6 core beside the one in the wattmeter and you'll have a hell of a time trying to tell the difference. That is why I made the suggestion. The core should be of ferrite material instead of the powdered iron material used in the T-50-6 core.

February may mean many things to many people, but here in Baltimore, February is the most common time for the "big snow" to hit. Presuming that many of you may find yourself in that situation this time of year, I thought it might be a good

Amateur Radio Teletype

time to pull out that old mechanical teletypewriter and try to get it on the air.

Thanks to Dave Gearhart WA4GVT of Huntingtown, Maryland, I am in receipt of some basic information needed to get these machines running.

Figure 1 is a drawing of a Model 28 cabinet, showing the location of the various cables and terminal strips which

need to be accessed. The "C" terminal strip, which contains all the vital connections, runs across the back of the machine. As detailed in Figure 2, the cable connects to the top of the strip, with the permanent wiring coming in on the bottom of the strip.

Figure 3 shows a schematic diagram of the Model 28-RO (receive only) wiring, and should be helpful to anyone trying to resurrect an old machine.

Another popular machine is the Model 33-ASR, commonly used on computer circuits. This ASCII machine with Automatic Send and Receive capability (ASR)

can frequently be obtained from old computer mainframe sites, and can be used as a hard copy teleprinter, particularly when connected to an interface which accomplishes the ASCII-to-Baudot translation. Figure 4 is a similar schematic of wiring for this machine.

All in all, I hope this information is a useful addition to the attempts to get that old greasy piece of hardware on the air.

To get that computer on the air, don't forget the RTTY Loop software collection. At this time, there are three sets of programs available. Set One is the "original" RTTY Loop program disk, containing an assortment of RTTY and ham radio programs, containing the programs needed to deal with all of the commonly used archives, along with DOS and Windows shells. The newest collection, Set Three, has even more RTTY and ham programs. Each collection is about one megabyte of stuff, and will fill a 5-inch 1.2 Mb or 3.5-inch 1.44 Mb disk. If you send me 360 kb

Techno-Whizzy 1, Parts 1 & 2

Refer to the above article in the December 1992 issue, page 12. Diode D1 is backwards in the schematic diagram (Figure 3), it should be installed as shown in Figure 1 below. Note that the diode position is shown correctly in the parts placement diagram in Figure 4b. *TNX to Jean-Claude Abrazit for the correction.*

The Basic program to determine the diode placement for a given frequency has a typo in line 9000 ("0101" was entered twice instead of "0110").

It should read: 9000 DATA "0000","0001","0010","0011","0100","0101","0110","0111". As a result, the values shown in the accompanying sidebar entitled "Some Common QRP Frequencies for the TW-1" are in error and should be recalculated with the updated Basic program. *TNX to Jean-Claude Abrazit for the correction.*

In the January 1993 issue on page 14, the wire size was omitted for the output filter toroid windings (Table 1). It's best to use #26 enameled magnet wire.

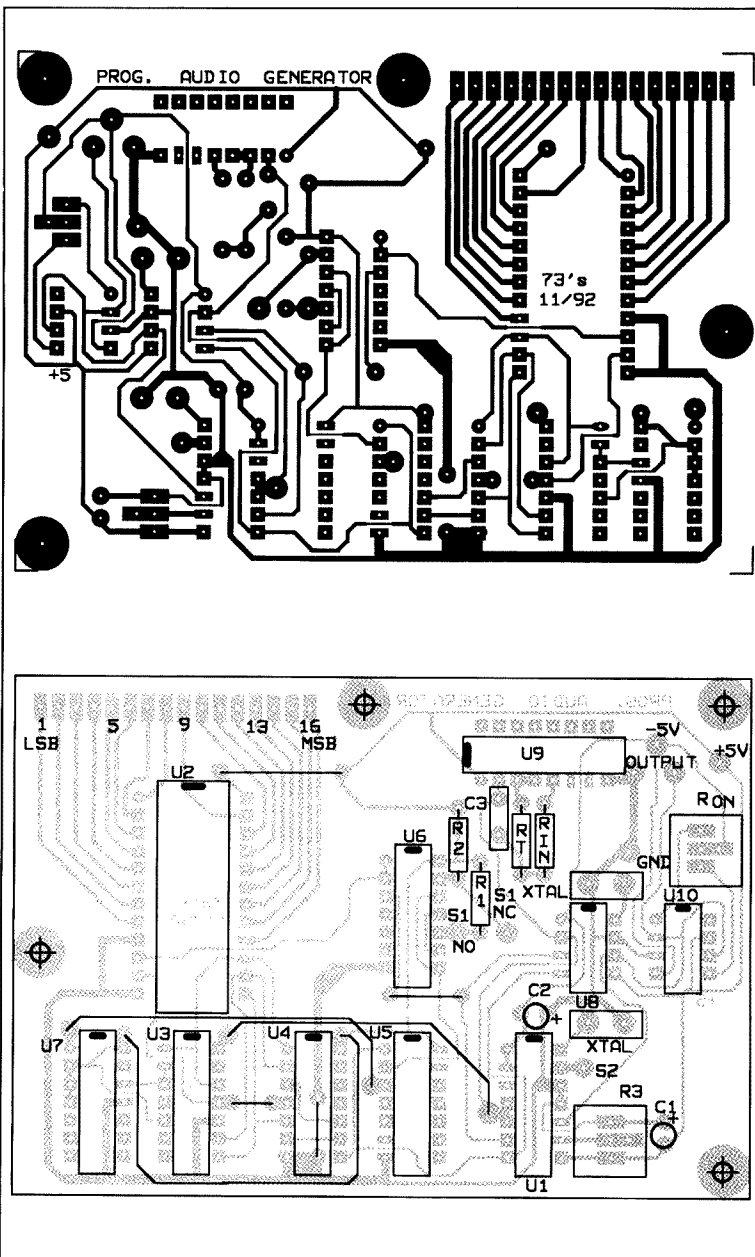

Figure 1. The corrected schematic of the Techno-Whizzy 1 voltage regulator circuit, showing the proper placement of diode D1. Refer to Figure 3 in the December 1992 issue.

9600 Baud Backbone— Lone Star Style

What do residents of Texas, Oklahoma, Colorado, Indiana, and Michigan have in common? Well, among some other possible answers, they've got a 9600 baud packet backbone called TexNet. Though the regional systems aren't linked, the Indiana-Michigan system (called GLNET, for Great Lakes Network), Oklahoma and Colorado systems use the hardware and software designed in Texas as a high-speed route for BBS forwarding and user traffic.

TexNet began in 1985 as a summer project for Texans Tom McDermott N5EG and Tom Aschenbrenner WB5PUC. The idea was to create a low-cost, high-speed backbone for packet radio traffic. By the October of '86 the system was operational, and Texas hams now have connections among eight cities, with more on the way. This expansion is thanks to the coordination effort by TPRS (the Texas Packet Radio Society), the organization championing TexNet. Unlike high-speed backbones dedicated to BBS traffic forwarding, TexNet was designed from the start to provide services to the end user, and to allow message forwarding.

Multi-Talented

In addition to the 9600 baud backbone connection, each TexNet node provides a primary and secondary user port designed to communicate with the LAN (Local Area Network) where it is located. The usual case is 1200 baud AX.25 ("normal" packet), but other protocols can be supported. This makes direct access to the high-speed backbone readily available to users for connections to remote stations in range—direct or via digis—of a TexNet node. The system makes long distance keyboard-to-keyboard QSO operations not only possible but fun.

If that isn't enough, how about adding local digipeater service, a mailbox, and a pair of conference bridges for round-table nets? Looking at everything a TexNet node provides, TPRS's description of one as a "multi-resource" is fitting.

The Hardware

The heart of a TexNet node is a TPRS NCP (Node Control Processor) board. This board has connections for a pair of radio modems, also available from TPRS. One of the things that makes a TexNet node inexpensive to implement is the choice of RCA 700 radios for the 9600 baud side. These are land mobile service, mobile radios which can often be found surplus at a low price. They are easily tuned into the ham bands, and are very rugged. Any appropriate radio can be

used on the 1200 baud side. The low cost and simple nature of the hardware makes TexNet an attractive option for areas wanting to build a backbone.

GLNET

So attractive, in fact, that when a first effort at a Northern Indiana-Southern Michigan backbone on 6 meters fizzled in 1989, the Michigan sysops latched onto TexNet's already integrated design as the answer. Over the next year, things started to happen in Indiana, too. Today, GLNET will get you keyboard-to-keyboard from as far south as Franklin, Indiana, using the Indianapolis node (atop the State Office Building) to Mount Pleasant, Michigan, north of Grand Rapids (more than 300 air miles). TexNet nodes are easily interfaced with the more common networking schemes, such as TheNet and KaNodes. This means that the usable coverage of the GLNET system is extended from each node by these other systems.

A TexNet network is also a great way to provide special data services to end users. The GLNET system offers a centralized mailbox, a weather server, and—thanks to N8IMO in Grand Rapids, Michigan—an Internet gateway. For those not familiar, the Internet is an enormous network of government, educational, and commercial computers all over the world. It is a patchwork of technology, with everything from high-speed (56 Kilobits per second and up) backbone segments, to 1200 baud dial-up connections keeping the data moving. The Internet uses a protocol called TCP/IP for Transport Control

Protocol/Internet Protocol. This is often referred to as simply "IP." IP has some advantages over the AX.25 (Amateur X.25) protocol typically found on packet radio networks, and most TNCs can be made to run IP directly; however, it is not an easy thing to get going. There are many pitfalls in getting TCP/IP running; if you are interested, find an IP Elmer.

Hams use the Internet through what are called "wormholes." An Internet wormhole is accomplished by a technique called encapsulation, where a TCP/IP packet is wrapped in another TCP/IP packet. Why is this necessary? Because on each end of a wormhole are radios, and the users of those radios must be licensed. Encapsulation ensures this by hiding the actual destination, preventing users who did not start from an amateur connection from getting into a place where their data could end up on the air.

The N8IMO TCP/IP mailbox offers AX.25 users a way to connect to the wealth of resources available on the Internet. In addition to being a full service PBBS itself, N8IMO offers users telnet services. Telnet is an IP utility that allows users to log onto remote computer systems—the same way you would if you were to dial up. The difference in this case is that it is accomplished across the Internet, not phone lines. With telnet, an Internet connected user can hop all over the globe. N8IMO, for example, offers connections to the University of Michigan, where there is both a weather server—provided by Zephyr of Massachusetts—offering all of the NWS (National Weather

Service) text weather products, and a geographic server—which can tell you the elevation, longitude, latitude, and other vital geographic data for most places in the world.

With Internet telnet, connections to nearly anywhere is possible—Australia, the Netherlands, Canada, all over the US—just about anywhere there is a ham and a university. Personally, I find it amazing to have fast, reliable communications with amateurs in Australia, completely independent of propagation conditions. Some may argue, "It uses land lines—it's not ham radio." Perhaps it is not DX, and QSL cards for the contacts wouldn't be very meaningful, but this sort of reliable, routine communications—previously available only to local or regional repeater systems—lifts ham radio up to a new level, in my opinion.

Easy to Use

The TextNet software is very simple on the user side. It has a minimal command set that is easy to remember. If it has a shortcoming, it is cryptic error messages—which are often only indicated with a number. Without a list, you're lost. Figure 1 shows a typical session with the Indianapolis GLNET node (Indy). You can see that the first step is to connect—via normal AX.25—to the node itself. TextNet convention has the node using the SSID (Secondary Station ID) of 4, so I could have connected to WA9ZCE-4. Instead I used the nodes alias. Once connected I am presented with the Network CMD? prompt, which indicates that the node is

ready for my commands. Typing "?" at this point would get me a brief list of commands. I knew that I wanted to connect to the NBIMO gateway, so I entered "c grip @ ngrapid."

"C" is for connect, just like you are used to on your TNC. "GRIP" is NBIMO's GLNET alias—for Grand Rapids IP. The "@" indicates that what follows is a GLNET node. The same method can be used to connect to any station in range of a GLNET node. For example, to connect to my station, a user could type:

c nlewo @ indy

Or, if I wasn't able to connect to the Indianapolis node directly, up to two digis (digipeater) could be included:

c nlewo v eocmbx @ indy

Here the connection would be made via eocmbx—the alias for the Johnson County, Indiana, RACES PBBS. Other simple TextNet commands are:

C CQ@ (node)—sends a CQ message from the specified node.

B—disconnects.

L—lists the locations of all known nodes.

M—connects to the designated message server (mailbox).

M@ (node)—connects to a specific message server.

S@ (node)—displays various connection statistics for a node.

S Y@ (node)—yesterday's stats.

As you can see, TextNet is pretty easy to use. Its designers intended it to be used by the general packet community and so made an effort to make it easy. This easy-to-get-along-with orientation

Figure 1 shows a typical GLNET session with the Indianapolis node. In this case, I connected to the NBIMO Internet gateway, whose alias is GRIP. NBIMO's software has been modified to recognize a GLNET connect and to adjust the callsign appropriately. See the text for more.

has also made its integration into existing networking schemes especially easy.

How Can You Get Involved?

If you are in the service area of GLNET (Indiana, Michigan, and surrounding states), try contacting IDEA (the Indiana Digital Experimenters Association) for information on supporting or expanding GLNET (more good node locations are al-

ways welcome).

For membership information, contact: IDEA, Les Catlin KD9LP, 219 Woodland Hills, Peru IN 46970. If you are in the TextNet service area, or would like information/equipment to start your own TextNet backbone, contact: TPRS, P.O. Box 50238, Denton TX 76206-0238.

Special thanks to Tom Frisz N9DD for information on GLNET. 73 de N1EWO.

What's New?

Lots of new things have been happening in radio technology. Let's take a break from the repair theme this month and look at some of the new developments and how they affect us.

Digital

Aren't you sick of that word? It seems like you just can't get away from it! Is there anything made today that isn't digital? Well, the basic guts of receivers and transmitters are still analog, but with digital control. That, however, is slowly changing as advances in IC manufacture make possible very-high-speed chips. These new silicon products are opening up all kinds of exciting possibilities. Let's look at a few.

DSP

Digital Signal Processing is going to change our radios, and it will be a very positive change. Already there is a product being marketed to hams which can improve HF SSB quality to something approaching the wired telephone. I

haven't actually tried it, but I suspect it works pretty well because it is an offshoot of a military product. The basic idea is to put a low-frequency pilot tone in with the audio on transmit. Also, the transmitted speech is processed to permit maximum intelligibility. The real trick, though, happens during receive. The unit at the receiving end detects the pilot tone and analyzes it to determine how it has been affected during its trip. Then, a digital signal processing chip compensates for the various kinds of degradation. That, along with dynamic expansion to undo the transmitter's speech compression, goes a long way toward restoring the original voice quality. Finally, new DSP techniques permit real-time analysis of the speech signal to remove noise and static. The result is that most of the garbage is removed, making the processed signal sound tremendously better than regular old SSB. And, it doesn't require one extra Hz of bandwidth to do it.

There are some trade-offs, of course. First, the inclusion of the pilot tone means that some transmitter power is being "wasted" on something other than your voice. In a way, it's kind of like having a carrier, except that it is much weaker than a regular AM carrier would

be, so the amount of waste is much smaller. In the long run, of course, the signal-to-noise gain of the system far outweighs the amount of lost power. Second, both radios need to have the devices for the scheme to work. I expect that eventually there will be an accepted set of standards for this kind of processing, allowing the system to be built into new rigs. I certainly hope that comes to pass.

Some receive-only DSP noise filters are already available. These range from notch filters which can remove multiple heterodynes to noise filters which can separate speech from static and adjacent-channel "monkey chatter." As prices drop, they'll get more popular.

Fast Modems

DSP is allowing the creation of some really fast modems. It is now common to send 14.4 kilobits per second over standard 5-kHz telephone lines. For that matter, compressed-format moving video is being sent along with digitized voice on the same lines. I wonder how long it will be before we send digitized voice over our allotted 3-kHz bandwidths. Hey, I wonder if anybody has managed to send the AT&T videophone's signal over the radio. I suspect it may use a synchronous modem system, which would make that impossible, except perhaps on VHF or UHF full-duplex links. Has anybody messed with it?

True Digital Radio

The ultimate use for DSP would be

to make the entire radio digital. Incoming signals would be digitized at the antenna, perhaps after one stage of amplification. Tuning, filtering and detection would be accomplished through digital signal analysis. The resulting bit stream would pass through a digital-to-analog (D/A) converter. An amplifier and speaker would be all that would be left! Imagine a multimode receiver with digital tuning, variable passband, memories, the whole works, that you could wear on your wrist. It's going to take awhile, but it will happen. I suppose you couldn't wear much of a transmitter because of the power requirements, but the same DSP technology can and will be used in full-sized transmitters. The only analog parts will be the RF power amplifiers.

DDS

Direct Digital Synthesis is a new technique for generating local oscillator frequencies. Until now, frequency synthesizers have suffered from some wobble and jitter (called "phase noise"). This aberration causes various symptoms, the most annoying one being muddy, hissy receive audio and an apparent widening of the receive passband. Although synthesizers have improved quite a bit over the early designs, the problem couldn't be completely solved because it is inherent in the design; as long as an analog oscillator must be kept on frequency through constant correction, it will wobble around its center frequency. Now, there's another way.

In a direct digital synthesizer, there is

UNIVERSAL RADIO HAS MOVED

Universal Radio has moved four miles to its new expanded location. We are now only 15 minutes from downtown Columbus and the Columbus airport. Visit our big operational showroom. We carry all lines of new and used shortwave and amateur equipment. Get a hands-on look at that new rig you have been thinking about!

HUGE COMMUNICATIONS CATALOG

The new Universal Radio 100 page communications catalog covers everything that is new for the amateur, shortwave listener and scanner enthusiast. Equipment, antennas, books and accessories are all shown with prices. This informative publication is available FREE by fourth class mail or for \$1 by first class mail.

Since 1933

no analog oscillator. Instead, sine waves are built up as a series of digital steps and then low-pass-filtered into clean, jitter-free waves. It might seem that the step-like nature of the sine waves would make them rather distorted, but that just isn't the case. If enough steps are used, the distortion frequency will be much higher than that of the sine wave itself, and it becomes fairly easy to filter the junk out. The filtering leaves lovely, smooth waves. Exactly the same technique is used to reconstruct the music signal in CD players, and you know how great they sound!

So why haven't we been doing it that way all along? Well, in order to have plenty of steps, the chip must operate at many times the speed of the signal we want to create. For music, that's not too hard because we don't need a signal over about 20 kHz anyway. But, when we want to generate signals in the multi-megahertz range, it's another story. Until recently, the D/A converters and related circuits just weren't fast enough. Heck, 10 years ago the average desktop PC ran at between 1 and 5 MHz. Now, 50 MHz computers are common, and even faster ones are coming soon.

The advantages of DDS over previous synthesizer designs are very reduced phase noise (in other words, spectral purity), ability to settle to a new frequency quickly (great for spread spectrum and split CW), and smaller tuning steps. Some DDS rigs can tune in 1-Hz increments! Do we need such precision? It sure doesn't hurt. It seems

like overkill now, but it may become important later on as synchronous signal processing schemes are devised. Those schemes may require that the transmitter and receiver be on precisely the same frequency. Of course, the master reference oscillators driving those synthesizers will have to be improved in order to back all that precision with equivalent accuracy. It's not of much use to be tuned to within 1 Hz if it ain't the right 1 Hz!

There's one other advantage of DDS: simplicity. Without all the analog parts, a DDS can be reduced to a few chips. The insides of those chips may be complex, but the resulting circuits can be quite simple. Are there any disadvantages? Just one that I can think of: cost. Right now, high-performance DDS parts are expensive enough that traditional synthesizer designs are still competitive. That's changing, as it always does, and I expect DDS to completely take over in the next few years. Today's non-DDS rigs will soon seem nearly as antiquated as all-analog rigs do now.

Power, Please

The weakest link in modern electronics still is power. Sure, there's no problem if you're near an AC outlet, but batteries are positively primitive. Nickel-cadmium batteries are an old technology that never worked all that well unless the cells were used under carefully controlled conditions. If you've owned your walkie for more than a year or two, you

know what I'm talking about.

That's changing too. New nickel-metal-hydrate batteries are coming. They have about twice the energy of NiCds, and there's less "memory" problem as well. They're rumored to be coming to ham radio and camcorder applications soon. I'll let you know more as I learn it.

There haven't been any recent breakthroughs in power supplies, but switching supplies are evolving and getting quieter. The old ones made an awful lot of RF noise, which limited their radio applications. Better shielding and design are resulting in cleaner supplies, and I expect them to start showing up more and more in HF rigs. Their primary advantages are size and weight; they can be dramatically smaller than linear supplies of equivalent power output. Historically, switchers have had reliability problems, but those have been pretty well solved, due to the popularity of desktop computers, all of which use switchers. In fact, the little wall cube which powers my laptop is actually a miniature switcher, as is the small supply for my camcorder. I look forward to seven-pound, 100-watt HF rigs with built-in AC supplies. With today's surface-mount technology, it should be possible to make an HF rig the size of a large 2 meter mobile rig. Sounds good to me.

Let's look at a letter:

Dear Kaboom,

My Alinco model 110 2 meter rig has an odd problem. In the low power posi-

tion, it works fine. In the high power position, however, the transmitter draws more than 25 amps for a moment and then it drops to zero, with no RF output. It seems to be clamping itself off, but I don't know why. Any ideas?

Signed,
On-Off

Dear On,

25 amps?? Yikes, at 13.8 volts that's 345 watts! Something's breaking down here. I agree that it's shutting off because the clamp circuit is working, but the question is, what's causing that huge current drain in the first place? I suspect the final output transistor. It may work fine at lower power and break down when full power is applied to it. Or, it could be a capacitor or other part in the output filter, or even a bad connection. More than likely, though, it's the silicon. If the transistor is discrete, you can try changing it. Of course, that will force you to do all kinds of adjustments, some of which may require specialized equipment. If it's a module, the whole module will have to go. Because this problem is so hard to determine, though, I'd send it off to Alinco and let them do it. After all, it sure wouldn't feel too good to shell out for a new output module and then discover that the real problem was something like a bad capacitor or antenna connector. Hey, here's a thought: Are you sure your antenna or coax isn't breaking down? Try using another antenna system before you do anything else. Good luck!

Until next time, 73, all, de KB1UM. ☐

NOW YOU CAN AFFORD THE BEST!

Engineered for the Ham, the finest in Crank-Up, Free-Standing or Guyed Towers is from Tri-Ex. For over 30 years, the INDUSTRY standard-backed with Defense and Aerospace technology.

MW SERIES

Self-supporting when attached at first section - will hold normal Tri-Band beam; 25', 33', 50', and 65' heights.

W SERIES

Aerodynamic tower designed to hold 9 sq. ft. in a 50 MPH wind at 36' and 51' heights. 67' tower rated for 6 sq. ft.

LM SERIES

"W" brace motorized tower. Holds large antenna loads. Models at 37', 54', and 70' heights.

TM SERIES

Tubular construction for larger antenna loads at 70', 90' and 100' heights. Free standing, with motorized operation.

MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.

The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator!

Multiple Independent Repeater control
Up to 5 Duplexed Links
Up to 4 different Remotes
Recorded Natural Speech Telemetry
Programmable Macros
Connect / Disconnect multiple Ports
Internal Receiver Squelch processing

Easy servicing
Integrated Autopatch
Expand at any time
Programmable Scheduler
+10v to +14v Supply
Standard 5.25" Rack Mount
Card-Cage design

▼ ELECTROMAGNETIC FIELD METER ▼

Reduce exposure to potentially harmful electromagnetic fields. AlphaLab's handheld TriField™ Meter measures AC electric fields, AC magnetic fields and radio/microwave power density. Find ground faults, AC current wires or measure high-field generators with the *Magnetic* setting (.2 - 100 milligauss, 60 Hz); identify poorly grounded or shielded equipment, high VDT or fluorescent light fields, distinguish hot vs. ground wires with *Electric* setting (.5 - 100 kV/m, 60 Hz); measure antenna radiation patterns, leaky microwave ovens, etc. on *RF/microwave* setting (50 MHz to 3 GHz, .01 to 1 mW/cm²).

Electric and magnetic settings are omnidirectional, measuring full magnitude of fields without the need to reorient the meter. Price of \$145 includes delivery and one-year warranty.

AlphaLab, 1272 Alameda Ave, Salt Lake City, UT 84102
Call (801) 532-6604 for speedier service or free literature on electromagnetic radiation health risks.

RANDOM OUTPUT Continued from page 88

grammar and punctuation and use it. The same thing goes for a dictionary. When a manuscript crosses my desk with spelling errors and errors in basic grammar, my first thought is, "What else did this guy get wrong?"

Any manuscript you submit should be typed, double-spaced, on standard bond paper (like photocopy paper, not that thin so-called "typing paper" you can buy in stationery stores). It is becoming a common practice to include a computer disk containing the text file of your manuscript. IBM format is still the standard, but Macintosh is becoming more and more acceptable (especially in publishing). Include a copy of your word processing document (most can be transferred to whatever the publisher uses), and also include a standard ASCII text file, just to be sure.

It is considered unprofessional to submit the same article to more than one publisher at the same time. This is called "simultaneous submission" and most magazines (including 73) will not even consider a manuscript that is not offered exclusively to them. If the magazine rejects your article, then you can try again somewhere else. Make sure you mention that your article is being offered "exclusively to 73" in your cover letter (if you don't know what a cover letter is, buy a book on free-lance writing and look it up).

Every once in awhile we get an article where the author, in trying to sound like a "professional writer," will say something like, "... and I can offer you one-time worldwide rights to this fabulous article for only \$500!" This is an immediate tip-off that this person is not only unpub-

lished (no problem, many of 73's writers are first-time writers), but he is also uneducated (which is inexcusable, when you consider how many books about free-lance writing are available). Every magazine has standard policies regarding pay rates and publishing rights. 73 pays anywhere from \$50 for a short filler to over \$200 for longer, more involved articles (*Radio Fun* pays a bit less, usually between \$40 and \$120). We buy first-time North American and reprint rights. We do not negotiate (neither does any other magazine I know of). This is the way the business works, and anyone who tries to stipulate pay scale and publishing rights (at least in this market) is showing their ignorance.

What We Need—What We Don't Need

73 is always looking for good construction articles, antenna articles and tutorials on new or different modes. We love to get good "how to" pieces on club activities, amateur radio PR and just about any other subject that your fellow amateurs might benefit from. Make sure you include several clear photographs.

73 does not generally publish fiction, nostalgia or what are commonly referred to as "human interest stories." *Radio Fun* does publish a certain amount of human interest stories, though, so it wouldn't hurt to send one in.

I hope I've answered some of your questions. Even more, I hope I have prompted a few of you to take the plunge and try writing for us. You won't get rich, but I can tell you that there's nothing like the thrill of seeing your name in print the first time.

HAM HELP

Number 31 on your Feedback card

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS Special Events Message Area, #11. (2400 baud, 8 data bits, no parity, 1 stop bit.) Tel. (603) 924-9343. Please indicate if it is for publication. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

WANTED: Service Manual for Regency Scanner Model ACT T16K. Lisle T. Hines K2QLA, 11 Meadow Dr., Homer NY 13077-1214.

Service information wanted for: CONAIR Model 452 synthesized transceiver; SILTRONEX Model 90

VFO; SAILOR Model RT144 Marine transceiver. I will pay copy and shipping charges. Errol May, P.O. Box 362, Buffalo NY 14207-0362.

I need replacement or repair for the modulation transformer Heath Kit Apache transmitter TX-1, part #51-34 or equal. Please advise. Ben Gelfand, 81 Macy Rd., Briarcliff Manor NY 10510.

I just purchased a brand new 10 watt Motorola speaker Model SSN 2005B. No instruction sheets came with it. The pin-out info sent to me by Motorola hasn't been much help. No matter which wire I feed to my audio, I still can't get anything out of that speaker. Does anyone out there know of a simple hook-up to make use of the internal amplifier? N.B. Sadorian N6WGX, 500 Via Val Verde, Montebello CA 90640.

NEEDED: Manuals, schematics, anything for Hammarlund HQ120/HQ129 receiver, and Hallicrafters S-38C receiver. Thanks. Robin Okelly, 39400 Howard Rd., Marcola OR 97454. (503) 933-2217.

BASIC REPEATER INTERFACE

ONLY \$50!

Have your own repeater or link system!

Easy repeater setup without modification to your radio gear, simply plug in and go! Ideal for emergency or portable/mobile repeaters! NEVER SAY DIE

Continued from page 4

product, it's almost enough to make me wonder.

What To Do

This New Hampshire Economic Development Commission thing has been fun as well as frustrating. It's gotten me to read dozens of books, participate in dozens of conferences and subcommittee meetings, hear testimony from educational and financial experts, and work with some outstanding New Hampshire businessmen.

When I discovered that the Commission was being controlled by politicians and was going to be prevented from any possible success, I started sending the other Commission members reports on what I was discovering. I came up with creative proposals for solving our major state problems. I made proposals for cutting crime by about 80%, the cost of government by 50% within five years, education by 30% (with a far better educational result), eliminating welfare costs, creating thousands of new jobs, and so on. These reports were published in my book, *We the People Declare War on Our Lousy Government*.

Since publishing the book I've been continuing my reports to the Commission, with creative approaches to cutting health care costs, going into more detail on educational changes, and many other ideas. These are being published two or three times a month as *What To Do*, with six having been published as of this writing. If you're interested in this series they're available by subscription for \$10 a dozen. They're worth a hundred times that.

Of course the chances are that you really aren't interested in solutions to unemployment, crime, health care, our educational mess, our crooked Congress, the deficit, welfare, and so on. Not even interested in being able to talk about these things on the air since that might interrupt your memorized spiel. So I don't suppose you'll want to get the book or the newsletter. The book is \$10 from Uncle Wayne's, plus \$3 S/H per order. You can save money by getting a 20 wpm practice tape at the same time. And maybe a handbook. Something to read on those long February nights after the DX bands have died out.

Magnetic Fields . . . Again

An article in another ham rag pooh-poohed the dangers of being exposed to 60 Hertz magnetic fields, citing the IEEE as a source of the pooh. Just in case you have any question about magnetic fields causing your body harm, you should look up the new article by Paul Brodeur in the Dec. 7, 1992, issue of *The New Yorker* and see what's going on.

Paul's persistence broke the lid off the damage asbestos in schools was doing to our children, despite the insistence of scientists paid by the asbestos industry that there was no danger. He was opposed by a similar pattern of paid-off scientists when he blew the whistle on the Love Canal mess. Now it's the might of the electric power industry, which is faced

with who knows how many billions of dollars in litigation over the deaths it has knowingly caused, plus the costs of making our homes, schools, and work places safe. This will easily dwarf the savings and loan costs, so one can understand why the utilities are fighting such a desperate battle.

The government has been one of the big bad guys in all this . . . in the name of not causing panic. What would happen if Americans suddenly became aware that nearby power lines, pole transformers, and even their electric blankets are killing or damaging their children, causing miscarriages, and hastening their own deaths? Paul picked one particular California school for his article. The wonder to me is that, considering the evidence of such a high incidence of cancers and tumors in teachers working on the side of the school near the high tension lines, Paul was able to be so patient in reporting the government and power company cover-up.

The Dec. 14, 1992, issue of *U.S. News* (p. 94) added an even darker side to all this with a report on the effects to men's sperm when they drink alcohol, smoke cigarettes, or take other drugs. It's turning out, according to a March of Dimes research report, that these all have a profound influence on the resulting child. I've been writing about the impact of drugs and emotional problems on children in the prenatal period. Now I'm going to have to go back one more step and include preconception influences on a child's life.

If drugs and other shocks to the system during the preconception or prenatal periods can cause miscarriages, is there any question that when slightly less damage is done we're likely to have children with damaged DNA to try and raise and educate?

One of the shocks to every cell in our bodies is our exposure to power-line magnetic fields. These fields are affecting us . . . including men's sperm and women's eggs. They're affecting children permanently in the prenatal months. Later on they're gradually wounding or killing our children . . . and us.

I've been writing about this for several years. Have you been shrugging me off or have you gone out and bought a milligauss meter and swept your home for dangerous fields? How about your work place? I've recommended that ham clubs, as a public service, buy meters and offer to sweep local homes and offices. I haven't yet seen one single example of a club doing this reported in a club newsletter.

Here we are, an almost unknown hobby . . . one desperately in need of PR . . . and we're going to lengths to hasten our own death as a hobby by avoiding PR. I've mentioned lecturing to college classes on entrepreneurialism and finding that maybe two or three percent of the kids have ever even heard of amateur radio! Then there are the reports of police stopping mobile hams and not even knowing about the hobby. How much is it going to take to get ham clubs to start being responsible?

Have you already forgotten how the

ARRL refused to cooperate with a researcher checking into ham deaths by cancer to see if our proximity to magnetic fields might be hurting us? He found that hams were dying at double the average rate. Did you read that in *QST*? Well, it's no wonder if your ham shack is anything like mine. My main rig was okay, but my amplifier was radiating a death-dealing magnetic field. If a few ham widows started suing amplifier manufacturers we might see them at least suggesting that their amplifiers be positioned several feet from the operating position. A few hundred million dollars in lawsuits might get their attention.

In the meanwhile, we're sitting there being gradually and silently destroyed by the radiation around us. Worse, we're passing on this damage to our children in the form of damaged sperm.

Our amplifiers are particularly nasty death-dealers because not only are they radiating strong magnetic fields, but these fields are varying as we key our rigs or as we talk on sideband. The deaths near power switching stations and to power company workers has shown that transients are even more destructive to our cells than steady fields. You may have read the recent reports on facial cancers and their connection to electric razor use.

The power companies know what's going on. The asbestos industry knew for years what their product was doing to people. The cigarette industry has known for decades what their product has been doing, yet they're still publicly denying there's any proven relationship between cigarette smoking and death. Just coincidence. If the coincidence of death hits you, will your widow blame the manufacturer of your linear and go after them?

When the coincidence of a defective child hits, will the family go after the manufacturer of their electric blanket? Or the power company for putting that distribution transformer just outside their home? Or if it's a ham's child who's been harmed, will an amplifier company be asked to pay?

It's easy to recognize miscarriages and leukemia. It's easy to recognize brain cancer and other major reactions to magnetic fields. But what about the less than death-dealing changes all these carcinogens are causing? What about less obvious illnesses, personality problems, learning disabilities, dyslexia, and so on? There's no reason not to expect a whole array of abnormalities to result.

One of the leading research scientists in this field is Bill Adey K6UI. I've put a long list of the research papers he's authored or recommended on the 73 BBS. His research on the effects of distressing low levels of magnetic fields on cellular growth leaves no room for doubt that these fields are far more destructive than people ever imagined.

We know that every living cell lives and communicates via minute electric currents. We also know that when we put any kind of a conductor into a magnetic field it generates a voltage in the conductor. So why should we be even slightly surprised when we find that our body's cells are being screwed up

by stray magnetic fields . . . some of them of relatively enormous intensity. We should be surprised if this *didn't* mess things up.

What do you do about all this? (1) Get informed. Read the Brodeur article. Get the book *Electromagnetic Man* by Cyril Smith, St. Martin's Press 1989, 344p, and also *Warning: The Electricity Around You May Be Hazardous to Your Health* by Ellen Sugarman, Simon & Schuster Fireside 1992, 238p, \$11. (2) Get or build a milligauss meter . . . or get your club to buy one. (3) Go on your local talk radio programs and get the word out, offering a club service to check on magnetic fields in homes, work places and particularly schools near high tension power lines. (4) Let me know what successes (or failures) you've had. (5) Get coverage in your local newspapers, showing this as a public service by your ham club. (6) Meet with your local school principal and arrange to talk with the kids about magnetic field dangers . . . and please don't forget to put in a big plug for amateur radio. It's a safe hobby as long as you keep the RF in the shack down and your death-dealing linear amplifier several feet from where you operate.

Money Talks . . . Again

In case you haven't been keeping up with the magnetic field situation, you might like to know that the Environmental Protection Agency (EPA) had a report ready to release citing electromagnetic fields as a probable carcinogen. This aspect of the report was blocked by the Bush White House Office of Science and Technology Policy on the basis that it "would alarm the public."

On September 30, 1992, Sweden's National Board for Industrial and Technical Development said they would be acting on the assumption that there is a connection between exposure to power frequency magnetic fields and cancer, in particular childhood cancer. This was the result of a five-year research program, following over 400,000 people, which showed a clear relationship between magnetic fields and childhood leukemia. They found that children exposed to more than one milligauss had twice the risk of leukemia. At two milligauss it went to three times the risk. Men exposed to 2.9 milligauss had three times the leukemia of those exposed to less than 1.6 milligauss.

So how about TV and computer terminals? In Helsinki the Institute of Occupational Health found that women exposed to three milligauss suffered miscarriages at three-and-a-half times the rate of those exposed to one milligauss . . . a result quite similar to the Swedish leukemia rate. The University of Adelaide's Department of Community Medicine found women working with computer monitors developing brain tumors at nearly five times the expected rate. There's also good reason to suspect that much of the elevated incidence of breast cancer may be VDT related, though I know of no study having yet been done to find out about that.

Will all this be enough to get the White House to back off? Will it force the elec-

tric industry to at least stop trying to stonewall the problem? In the meantime, thousands of kids are dying of cancer and probably tens of thousands of adults. Worse, we haven't even a clue as yet as to what cellular damage these fields are causing. We only count the dead, not the wounded. As I've pointed out before, we have no reason whatever to expect that children born of mothers exposed to these magnetic fields are going to be other than genetically damaged . . . it's just that the damage wasn't serious enough to cause a miscarriage.

All of which brings us to your home and your ham shack. If you have a pole transformer near your house, it's time to either get it moved or move your family. Check it out with a gaussmeter and make sure you're living in an under-one-milligauss field. Gauss out your shack, too. You're certainly going to have to move your linear several feet from your operating position, even if it's a nuisance to have to get up to tune it. And if your children are going to schools which are near high tension lines it's time for them to change schools.

In case you missed it, not only are these fields damaging your body, they're even damaging your sperm . . . which means that you have a good chance of permanently damaging your children's lives even before they're conceived. Of course cigarettes, alcohol and other drugs also affect your sperm and your wife's eggs before conception, or have you missed the recent March of Dimes research report?

What about HTs? We don't know yet, but there are some good reasons to believe that the use of subaudible tones may damage brain cells. Research has shown that our cells are able to detect HF, VHF, UHF and microwave energies, but it may be the demodulated components which cause damage.

What does it take to generate one milligauss? Well, I measure 1 mG at 30" from my laser printer and 2 mG at 18". I haven't used my laptop PowerBook Mac in my lap since measuring 25 mG leaking out the bottom. There's about 5 mG by the keys, and less than 1 mG at 3" in front of it. My electric blanket measures 150 mG . . . a death trap.

Help Wanted

Whoo, are we short-handed! With both 73 and Radio Fun growing, we need help. And that's not to even mention a couple dozen other projects we're all working on . . . like a "Wayne Green's World" TV series which will be promoting amateur radio, my book and music; a new series of amateur radio books; new publications in the vacation, video, and educational industries, and so on.

I'd like to find a couple hams with experience in newer communications modes . . . like packet, RTTY, and repeaters. An ability to read and write is critical, as is the ability to meet deadlines and have at least an outward appearance of being a human being. An Extra class license will be acceptable only if you cheated on the code test, otherwise we'll have to administer some tests to mea-

sure the extent of the inevitable brain damage which results from CW use . . . a semi-vegetative state known as Morse-Cauliflower Brain (MCB). This can be detected by (a) a loss of a sense of humor; (b) a hating of 73; (c) a totally without factual basis conviction that not everything I write is true.

If you're interested in living in New Hampshire, where we have the highest quality-of-living index of all 50 states; where we have vacationers driving for hundreds of miles to enjoy our state four seasons of the year, let me hear from you. Let me know what you'd like to do and what you've done so far that would encourage me to think you might be able to actually do what you propose. What have you accomplished in life so far? What have you to show? No, I'm not interested in the usual baloney resumes. I want some proof that you can write . . . that you have a sense of humor . . . and that you have initiative. And what's the big reward, if you win? A whole lot of work . . . work you'll love. Naturally this is made up for by a generous pay schedule . . . not! You and your family won't starve, but keep in mind that two of our staff had to sell their yachts recently. But isn't it a whole lot better to be doing something you really enjoy rather than that miserable odd job you've been wasting your life on so far? I know that once I got snookered into amateur radio publishing I was a goner for life.

The Great Twins Fallacy

Yes, I know you have absolutely no in-

terest in this, but who else am I going to tell? This has to do with all this baloney you've been reading . . . which makes the perhaps over-generous assumption that you have been reading . . . about what scientists have learned about genetics by studying identical twins separated at birth.

The results of the studies have been amazing. Twins turn out to often smoke the same cigarette brand, be married to wives with the same names, name their children the same names, and so on. Golly, how astounding that all this is genetic.

Even the gays have been cheering at studies which show that about 50% of identical twins are both gay when one is. Genetics at work, obviously.

Maybe. Maybe not. I think we may be able to rule out a lot of the coincidences between twins if we start investigating the possibility that there is some sort of completely unconscious communications between twins. That isn't too difficult a concept to consider, is it? Since there are millions of people who've experienced some kind of ESP communications, we know that there are times when this happens. We haven't had much luck in repeating it on demand. Scientists are very unhappy with non-repeatable experiments. Most of 'em refuse to accept anything non-repeatable as even being possible.

Having personally experienced such communications where there was not even the remotest possibility for it to be a coincidence, I know it's possible. We just have to

learn more about it . . . and refusing to investigate the phenomenon because some scientists believe it's impossible isn't a very good scientific approach.

Anyway, the next time you read a report on how amazingly similar twins separated at birth are, forget the genetic implications. Sure, there may be some, but they aren't going to be isolated this way.

We do need to see if we can find out how people can communicate on a subconscious level. If we can make this repeatable we may be able to start sending QSL cards to confirm mental communications. Alas, at the pace we're moving now in our research on the mind it'll be another 50 years before we learn enough to harness its incredible power. Maybe a hundred.

Music, Music, Music

A note from Rob AA6BN claims that not all hams are nerds with no interests but ham radio, and henceforth I should tell you about my new music magazine. Now, while I doubt that Rob has one scintilla of evidence to back up his obviously ill-considered claim, on the mere wildest chance that somewhere out there, despite the dictates of reason, some of you might be interested in music, I'll tell you about one of my new projects.

Yes, I know, we all like music. But there's a whole of a difference between liking music and actually buying records . . . they're CDs these days. When I was a kid I liked music. I even bought a 12" RCA Red Seal 78 record of Strauss' Tales of the Vienna Woods and his Blue Danube Waltz when I was 12, to play on the lam-

ily wind-up Victrola.

I didn't get involved seriously in buying records until they threw us off the air when WWII started. Unable to ham, I turned to music and building hi-fi systems. In the 1950s, in addition to helping pioneer RTTY, I manufactured a new kind of loudspeaker which did very well. Alas, my RTTY interest sucked me into ham publishing.

When the compact disc came along in 1982 I started a magazine to help speed its acceptance. It eventually became the country's leading music magazine. Since I enjoy starting new publications more than running mature ones, I sold *CD Review* last year and started a new music magazine. If you're into buying music you'll enjoy, it since we mercifully review over 200 CDs each month. I know you'll find this hard to believe, but we don't take ourselves seriously. It's kinda like *Mad*.

The reader uproar over my editorials disappearing from *CD Review* got us to capitalize on this in our *Secret Guide To Music*. Our readership has turned out to be a bunch of men (95%) who buy 7.6 CDs a month, average age of 41, average \$57,000 income, 68% like classical music, and so on. If you'd like to see a copy drop me a line. You've been wanting to write anyway to tell me how you don't always agree with my 73 editorials, so this is a good excuse. My *Guide* editorials are shorter.

The same basic drive that keeps me publishing 73, a genetic defect which forces me to try and get others to share things I enjoy, is at work in my pushing people to

enjoy music. So I urge my readers to try classical music, ragtime, theater organ, and so on. Like a good book, a recording is something you can enjoy for the rest of your life.

To help make it easy for my readers to find interesting music, I've a mail order service. Far's I know, it's the only place any one can buy CDs and return them if they don't like them for a measly \$1 restocking charge. Love it or return it. And I've been turning out samplers to help people discover music they might otherwise have missed. We've produced nearly a hundred samplers so far and they're all totally, completely 100% free . . . except for an insignificant, hardly worth mentioning, \$3.89 S/H.

In A Rut?

I'm not sure why so many people get into ruts. I had a great time working DX, but after 300 countries confirmed I lost interest. I'd done that. I had a ball with RTTY for several years . . . then I'd done that. DXpeditions were fabulous fun. I won't forget one minute of any of 'em. But I've done that. It was exciting working seven states on 10 GHz, now that's done. I loved contests and won certificates for DXing, Sweepstakes, and VHF. Done. OSCAR was a challenge and great fun. I had one of the early repeaters back in 1969. Then there was Navy MARS. It was enormous fun pioneering NBFM, SSB and slow-scan. So I keep urging you to try new things . . . to find new excitement in our hobby, as I have. I tried aeronautical mobile in my own plane . . . fun. I've been hot air ballooning with my HT

and used it while skiing the slopes. If someone comes up with something new to do in amateur radio I'll probably hop aboard.

Then I talk to hams who have been exchanging signal reports and handles for 20 years or so and have done little else. How can I open their minds to the fun of trying satellite communications? Of working RTTY and packet? Of getting on top of a mountain and working DX on 10 GHz . . . way over in a neighboring state a hundred miles away? Of looking for a temperature inversion band opening and working through a repeater five hundred miles away? Of working a thousand miles or so on 2 meters via aurora skip? Or seeing if you can work 100 countries in one weekend? How about some 75m DXing? Now there's a real challenge! To do much of this you have to go up to the higher bands, make a DX contact, and then get 'em to come down to 75. I'll never forget the thrill of talking to my home station on 75m while visiting Ray VK3ATN and hearing W2NSD/1 coming through 5/9+. Wow! Have I ever shown you the aerial pictures I took of Ray's amazing antenna farm? He did a great job of working the U.S. on 2 meters via moonbounce.

Where's your spirit of adventure? How can I get you out of a rut?

And the same thing goes for music. There are a couple hundred different kinds of music. Some aren't all that exciting, but there's a lot of fabulous music you've never heard just waiting for you to reach out. Have you ever heard Gottschalk's Tarantella? How about Nazareth's music? Delius? Gliere?

Build a Super-Horn Antenna for 10 GHz Continued from page 14

waveguide adaptor that takes waveguide down to an SMA fitting.

Road Test

Finally, we were off to the test area where we could tune into the N6CA beacon about 40 miles away. Using a Kenwood 751 with the SSB Electronics transverter, we could barely make out the beacon with an omnidirectional 10 GHz antenna. A small ARR horn improved signals up to an S-4 level and a longer military 10 GHz horn (of a much more slender design than conventional horns) gave us an S-6 signal with tight directionality. We were now ready to give the Super-Horn the big test. We had quite a time getting it lined up with the transverter so that we didn't stress the delicate SMA connector. We knew we had a winner as we inched the equipment up to the horn: Reception to the distant beacon was coming in loud and clear, even before we were on the waveguide!

When the connection was made, the big horn

Photo G. No, this is not a rocket-assisted station wagon. Suzy N6GLF operates portable 10 GHz SSB using the Super Horn antenna.

Photo H. Side view of the Super Horn antenna. The two halves are joined at the top and bottom for maximum strength (i.e. each half has two bends in it).

pulled in the beacon at a fantastic S-9 level, better than we had anticipated. Side lobes were not as clean as the smaller horn, but at 10 GHz, that might be an advantage to find distant signals.

If you are already on 10 GHz, take out your standard horn antenna and see what you might do to easily extend its sides for increased gain.

Figure 3. An existing horn antenna can be increased in size for improved gain by extending the sides.

Notes from FN42

I missed a very interesting meeting several nights ago. Some of the local hams decided to see if there were other hams in the area who might want to develop an amateur radio club. I had to be very honest with them and say that I had heard that organized clubs don't seem to make it here in the Keene, New Hampshire, area. Many have started and many have failed.

That didn't seem to deter them. Through a mass mailing of 250 letters to hams listed in a ham data base for this area, 30 replied that they would be interested and would show up at the informational meeting. One of the hams, who is a DJ for one of the local FM broadcast stations, was able to get a meeting room at a local motel.

When the evening came there was a BIG surprise waiting for the organizers. Over 50 hams showed up, including the mayor, who is also a ham. I have only received tidbits of what happened at the meeting, but I understand that it was SRO (Standing Room Only).

As I am writing this, some of the hams who were at the meeting are discussing it on 75 meters. The discussion is very positive, even exciting! I have been involved in the starting of several clubs, ham and non-ham. It is always exciting to see that others share your visions. Most of the other clubs had a very definite purpose, such as DXing, contesting, repeater operation, etc., but this one, from the feeling of the group, seems to go in many different directions. Many of the attendees would like to learn more about ATV, traffic handling, packet, contesting, DXing, etc. Luckily we have many hams in the local area who have expertise in many of those areas, such as Bill Brown WB8ELK, ATVer and high altitude balloon experimenter; Dawn K1TQY and Alan W1FYR, who are dynamite with traffic handling; Joel WA1ZYX, Scott WA1YTW, and Buzz WA1NHP, who are actively involved in packet; and many hams who have been contesting and DXing for years, both HF and VHF/UHF. Plus, they don't want to spend most of the meetings discussing the management aspects of making it all happen.

I would be very remiss if I didn't mention the names and call signs of many of the hams who have had leading and supporting roles in this beginning effort: Doug and Deborah KD1GJ and N1NGC, Randy N1KWF, Gary and Karen KD1JR and KB1AGP, Bob KA1ZMF, Paul WK1P, Peter KA1ZRI, Buzz WA1NHP, Joel WA1ZYX, Scott and Ann WA1YTW and KA1QQH, and Bruce WA1YZN. If I left someone out of this list it is certainly not intentional.

As I review what I have written, one word seems to stand out in the previ-

ous paragraph, and that word is "supporting." An organization is only as good as the members supporting the leadership. Organizations live and breathe with the members, not the leaders. The leaders live only with the continued support of the members. How can you be a leader when there is no organization to lead?

I plan to continue my discussion of the starting of new clubs in the future because there may be many of you who wish that there was a club in your area but there isn't. It isn't that hard to start one; the hardest part is to keep it going! The club only continues if its members want it to continue. I just dug out my trusty Webster's dictionary and a short definition for "club" is: "persons organized together"; "organized" means: "place in orderly arrangement, unite"; and "together" means: "in a group, at the same time, with one another." That means that the members have to get involved and continue to be involved. And those of you who are presently members of a club, please read or re-read my January column and the letter in "Roundup" from Rainier Bautista DY9CKQ titled "CO, CO, CO... OUR RADIO CLUB IS DYING!" and don't let your club get to the level that OSCAR-MARBEL got to. Get involved and keep involved!—Arnie N1BAC.

Roundup

People's Republic of China China News from BY1QH, edited by Rick Hunter: There are two Tsinghua Universities in China—one is in Beijing, where BY1QH is located; and the other is in Hsingchu, Taiwan. October 17 and 18 saw a first-ever Jamboree-On-The-Air (JOTA) activity between the two universities on both sides of the Taiwan Straits. JOTA is annually sponsored by the World Scout Bureau and anyone may take part. A number of students spoke to each other and talked about things of interest and curiosity. Many would like to build up a "pen-pal bridge" between individuals and the student-run associations. Wang BV3AV, an EE graduate student, devoted a lot of his time getting things organized for this unprecedented 10-hour QSO.

BY1QH is preparing for the installation of an SSTV station but we are lacking some information on activating this mode. We need to learn about the scan converter and how the equipment is connected. Can anyone send us this information? We have heard that some articles were published in 73 in the past but we have no way of researching this. I'll try to do some research on this.—Arnie

Amateur radio is still a brand-new concept to many young men and women here in the People's Republic. As the country becomes more prosperous, we believe that there will be lots of people getting involved in ham radio as soon as the government allows. Under such circumstances, we

truly hope that our friends in the USA, Canada, Australia, Europe, and elsewhere come and visit us. We would love to have those visitors talk to our students in either English or Mandarin and spread the knowledge. Tsinghua University has a small but nice hotel on the campus which is a good place to stay. BY1QH will make arrangements for you, just let us know as early as possible.

VE7UBC, the University of British Columbia (UBC) Amateur Radio Society and BY1QH have successfully re-established the weekly schedule we held several years ago. Doug and Darby, two UBC graduates, talked with Rick on November 11th. The Canadians kindly introduced two other active Canadian university ARS groups—Concordia University ARS in Montreal and Ryerson Polytechnic ARS in Toronto. We are looking forward to getting in contact with them via the packet BBS system. BY1QH is very eager to get in touch with other university ARS groups. It would be great fun to talk with friends of the same age.

We are very happy to have received many messages via packet radio, especially from Jeff AA1LG of the Bronx High School of Science Amateur Radio Club. TUARC congratulates them for their activities and would definitely like to stay in touch.

We will be starting an amateur radio class at TUARC very shortly. The "two-boy vs. two-girl" combination will add more fun to BY1QH. All of them are students at Tsinghua and have a good command of English and great enthusiasm about SSB QSOs. I think that it is great that two YLs are interested in becoming hams because the vast majority are males.

Thanks to all who have been supporting our efforts. We would like to hear from all of you. Contact us via mail at: Rick Hunter, Room 316, Building 25, Tsinghua University, Beijing 100084, Peoples Republic of China, or via packet: BY1QH @ JA5TX.JPN.AS, or to George VE7CIZ @ VE7KIT#VANC.BC.CAN.NA.

Switzerland From the International Telecommunication Union Press: Moldova, Bosnia and Herzegovina have joined the International Telecommunication Union (ITU). The instruments of accession of the governments of the Republic of Moldova and of the Republic of Bosnia and Herzegovina were both deposited with the ITU on 20 October 1992, bring ITU membership to 174 countries. Moldova (also known as Moldavia), a former USSR republic, is bordered in the east and south by the Ukraine and on the west by Romania; it has an area of 33,700 square kilometers and a population of 4,335,360 (1989). Its capital is Kishinev. It became independent in August 1991 and became a member of the Community of Independent States (CIS) in December 1991. Bosnia Herzegovina is south-east of Croatia and west-northwest of Yugoslavia. Its area is 51,129 square kilometers and it has a population of 4,335,000 (1991). Its capital is Sarajevo.

REPUBLIC OF KOREA

Pusan 608-102
Republic of Korea

Happy New Year to all. There is a new club in Pusan! The Pusan Packet Users Club has had two meetings so far. The second meeting was at the Pusan Yacht Harbor (branch office of the KARL) on September 26, 1992.

The club packet repeater station is set up on the mountain of "Hwang Ryong San," and the frequency is 144.74 FM, 24 hours a day. We are also planning to build a repeater on 435 MHz as a duplex system soon. HL5BMM donated a transceiver to the club for this purpose.

My station now consists of an IBM PC/XT for data communications with an MFJ-1278. These are hooked into my new Kenwood TS-850SAT. I also operate portable with my Yaesu FT-290 at 2.5 watts. I am hoping to meet many new hams on 160m CW, because Korean hams can operate between 1800-1820 kHz.

ISRAEL

Ron Gang 4X1MK
Kibbutz Urim
D. Negev 85530
Israel

Six Meter Expansion Over a year ago a 50-kHz-wide splinter of 6 meters was opened in Israel, but for the benefit of Class "A" licensees only. Now this license class has a 200-kHz-wide band to work in—50.000 to 50.200 MHz. The Class "B" ticket holders have been allowed into the band (and presumably the Class "D" Technical codeless license—the first exams were just passed a week before the writing of this) from 50.100 to 50.150 MHz. In all cases, maximum output power may not exceed 25 watts and all operations on this band shall be on a secondary non-interfering basis.

Asia 100—Ahziv Island Since the 19th of September, 4X is also on the IOTA (Islands On The Air) map. It was the first time that, for several hours, Israeli radio amateurs activated a station from Ahziv Island, about one kilometer off the coast of Israel, in the Mediterranean Sea. Ahziv Island is not more than a rock about 100 by 60 meters, just barely above the surface of the sea, and on stormy days is completely covered by waves. Headed by Dov Gavish 4Z4DX, aided by volunteers Mark 4Z4KX, Eliezer 4X6DL, Gershon 4X6PW, Moni 4X6ZK, and Ziv 4Z9GAB, the group sailed for the offshore island, erected some dipoles and got on the air.

Ahziv Island is one of an island group in that area protected as a nature reserve, and as such it was forbidden to drill any holes for anchoring the antennas. Everything had to be self-supporting or tied by strings to rock protrusions. A lot of red tape had to be cut in order to procure permission from the various authorities. The easiest to obtain, of course, was from the Ministry of Communications, always ready to aid and issue licenses

with special calls, like the one used here, 4X0AI, standing for "Ahziv Island." All in all, some 1,050 QSOs were made, 330 of them in CW. Four bands could be activated; namely, 21, 14, 18, and 7 MHz, while operating most of the time simultaneously with two transceivers and, for short periods, even with three. The group managed in this short period of time (only 390 minutes of activity, the time permitted to remain on this island) to work 56 countries. There was no permission to stay overnight, just for those few hours. If the authorities check and find out that no damage whatsoever was done to the island, we can hope that repeats of this activity will be permitted in the future to enable all the collectors of IOTA QSOs to receive the needed QSL cards that will be sent for each and every contact.

In summation: The activity was highly successful and all the participants are congratulated on a job well done.

Israel Represented at Friedrichshafen The Ham Radio Fair at Friedrichshafen, Germany, has been rightfully called "Europe's Dayton," and attracts hams from all over the world. Chock-full of manufacturers' exhibits, national radio societies' booths, a huge flea market, and special presentations, this ham radio haven gets larger year after year.

This past summer the Israel Amateur Radio Club had an official booth there with our official representative being Naomi Dor 4X6DW. Naomi is

well-known as one of the net controllers of the European DX Net meeting daily on 14.246 MHz. Her OM, by the way, is 4Z4 Kilo Banana. Also on hand were Shalom Meltzer 4X4MS, well-known for his operations from many African countries, Ahron and Shoshana Kirschner 4X1AT and 4X6OL, Ruth and Joseph Obstfeld (the IARC chairman) 4X4CM and 4X6KJ, Yitzhak Markado 4X6ZH, and Gad Golan 4X6RT.

At the booth were films on special activities of the IARC, Keren Kayemet (National Land Reclamation Authority) films on Israel, 6,000 mini chocolate bars weighing 250 kilos (a gift from Elite, the country's largest producer of sweets) and miniature bottles of Israeli wines. Of course, there were specimens of all the different Israeli diplomas, IARC publications, and other goodies from the Israel Amateur Radio Club.

Okinawan Hams Celebrate the Re-Opening of Shuri Castle The re-opening of Shuri Castle was the big event during the month of November 1992 in Okinawa. The kings of the Ryukyu Kingdom, an independent state until the 1879 merger with Japan, regularly entertained emis-

saries from the Emperor of China in Shuri Castle. The castle, first built in 1395 and restored several times thereafter, was destroyed during a 1945 battle in which one-third of the civilian population perished. A group of Okinawa hams went on the air as JR6RL from Shuri Castle on the weekend of November 14-15 to celebrate the reopening of the castle to the public. Okinawans are rediscovering their strong links to China and their history as an important trading nation from the 14th through the 17th centuries. A novel and upcoming NHK national TV series entitled "The Winds of the Ryukyus" has aroused intense interest in the Ryukyu kingdom, which as a trading nation absorbed the cultures of China, Indonesia, and Thailand and eventually created a distinct Okinawan culture.

Okinawa lies 300 miles off the Chinese coast and halfway between Kyushu, Japan's southernmost large island, and Taiwan. Okinawa prefecture, the southernmost of Japan's 47 prefectures, has a population of over one million. Okinawa was for many centuries a borderland between China and Japan so Chinese influence on Okinawan history, culture and religion is very strong.

On the HF bands Chinese stations are often stronger than Tokyo stations. There are only about 70 stations, all club stations of one kind or another, in mainland China, but with many operators per station Chinese stations are often heard on the ham bands. Taiwan

now has 1,700 licensed hams and 1,200 ham stations, so much activity from Taiwan and mainland China is to be heard here on the HF bands. An Okinawan station can easily join in a round table with Chinese mainland and Taiwanese stations.

I often hear Japanese hams practice their Chinese with Chinese hams. The NHK Educational TV network has a weekly "learn Chinese" program—as it does for a variety of other languages, including English, Russian, Italian, and Spanish. So these hams can work on their Chinese systematically in a formal course right at home and then get on the air for language practice.

So far I have been able to exercise my Chinese in talking with stations in Tianjin, Nanjing, Shanghai, Fuzhou, and Hangzhou. I was worried about understanding Chinese ham slang, but they will oftentimes use English for special ham words. In Taiwan, hams are not only called hams but are also known as the sausage tribe (xiangchangzu). China now has about 70 club stations in schools, local government sports associations, and some factories. Most of the Chinese hams I have talked with have been YLs. They tell me that YLs are fully half the Chinese ham population. Wang Min, an engineering student at Zhigong University in Tianjin, a port city near Beijing, told me that of the 30 members of the Zhigong University ham radio club, 20 are YLs. China should be an excellent recruiting ground for the Young Ladies Radio League!

Mixers and Other Small Case Devices

This month I will cover mixers: prepackaged, home-brewed, and a few others. Applications for mixers are numerous. I will show how a surplus mixer can be used at 10 GHz in my home-brewed station. Most of the mixers to be covered will be the small commercially available hermetically-sealed types associated with Mini-Circuits Labs. Be aware that these are not the only types available as they do not need to be hermetically-sealed to work at high frequencies.

There is some confusion associated with this type of device in that not all devices in similar packages are mixers. They can be power splitters, mixers, phase splitters, attenuators and even amplifiers. These devices have become quite common in the surplus market, making their use very popular in most amateur design projects. Take a look in any *ARRL Handbook* for the last 10 years and you will find articles peppered with SRA-1s or similar type mixers. The beauty of these devices is that if you have to go out and purchase them, they are available right off the shelf and the cost is not prohibitive: under the \$20 mark.

First, let's cover mixers of the SRA-1 type. This type is made for operation up to 500 MHz and is one of the most popular mixers produced to date. It has been used and observed in so many different types of projects over the last 10 years that I think it is a household word synonymous with mixer.

The SRA-1 and its cousins are produced by Mini-Circuits Labs and are constructed using the double-balanced configuration shown in Figure 1. Case styles may vary, as well as the frequency and level (dBm) han-

dling capabilities of similar type devices available from them. Be warned: Mixers are not the only devices that can occupy similar case styles. I have observed people purchasing surplus PC boards with devices looking like mixers on them, only to find out later that they were not mixers at all. A quick scan of a catalog will identify the device you have. I find that attenuators, phase splitters and mixers comprise the most common devices found in surplus. I have not yet observed amplifiers in these case styles. Mini-Circuits Labs does provide several series of amplifiers fully packaged and some of them look very similar in case style to our mixer cases, but I have never seen one in surplus.

If you can remember all the part numbers in the catalogs you have no problem identifying surplus parts. However, we are not computers and we don't carry data books with us so just try to recall some of the more memorable devices when out scrounging. What I try to do is generalize my memory bank to common types and use the catalogs for others. There are just too many part numbers and variations to try and remember. Don't memorize the more specialized components, just form some mental note on the most popular devices to look for in surplus. That limits most mixers to the GRA, SRA, SBL, TAK, TSM, TFM and SAM type mixers. The following prefix on these mixers is not important at this time if the highest frequency of use is 500 MHz. Most mixers will work to these limits. Sure, some go much lower but the odds are that the device you will find is good to 500 MHz. The SRA-2000 and the SBL-11 are good examples of mixers that go up to 2 GHz and seem to populate surplus boards.

Re-Pack Mixers

Re-packs, as I call them, are nothing more than commercial mixers in a

Photo A. OZ1UM with his microwave setup in Denmark for 10, 24, and 47 GHz operation.

small pin configuration housing placed in a container that connects the pins to coaxial connectors. Most of the re-pack mixers use some of the previously described mixer products as their main component. Some of these mixers with coaxial connectors are denoted with the prefix of ZLW, ZAD, ZEM, and ZFM identifiers. They are constructed with easy-to-use coaxial connectors for bench tests and lots of other applications requiring sturdy packages and quick connect/disconnect coaxial connectors. They can be furnished with almost any type of coaxial connector. These mixers are usually much harder to locate in surplus than the pin-packaged ones previously described, and when they are available they have a higher price.

As I stated before, power splitters or power dividers are packaged in similar case styles and can be confused quite easily. The differences in some of them lie in the labeling of the component parts, such as PSC, or PSCQ or PSCJ. If the part you find has a "P" in the part identifier, you can be assured it is some form of phase splitter or combiner. There are variations such as the PDC identifier, which is a directional coupler. Again, packaged directional couplers use ZFDC, still retaining the "DC" notation directional coupler. It's just like the "PSC" or "SC" part denoting the splitter coupler above. With most Mini-Circuits components you can make a basic determination on the function by word similarity of their code identifier.

This can be depressing. Possibly I am giving up part of my gray matter for ransom by this description, but that's how I try to group the miniature parts in my mind. The trick is to remember in generalities how the scheme works and make some rules for your use. It's necessary when looking at surplus PC boards as you never seem to have the proper catalog along when you find something interesting.

There are exceptions to any rule but in this case they seem to be unusual components and there aren't enough of them to worry about. For detailed information, contact: Mini-Circuits Labs, P. O. Box 350166, Brooklyn NY 11235-0003; (718) 934-4500.

Be aware that there are also filters,

RF solid-state switches, and even RF transformers available. If new demands are present and the market wants them I suspect almost anything that can be produced will be put into a similar package for ease of use. Please note that this is not the only company that manufactures this device but it is the most popular from both an advertising and a surplus availability basis. See Figure 2 for some of the more popular case styles. These units all look alike and even have the same pin counting method, so just consult a catalog for your device on pinout connections. In most cases a blue insulating bead lets you know which pin is pin #1.

Open-Frame Mixers

The market is also saturated with open-frame mixers constructed on small PC boards in the open. They are used in cable TV converters and even in amateur radio transceivers. These are configured the same but are constructed using discreet components instead of the prepackaged types. I am not sure that this is cost effective, but in any case the circuitry is quite the same. The basic diode mixer is connected in a quad double-balanced mixer configuration. This ring of four diodes has input and output toroid transformers connected in such a way as to form three ports.

The primaries of these two transformers are the actual input and output for the mixer, while the center tap of one secondary serves as the third port, the IF port. The other secondary center tap is grounded in normal operation. The input is the "L" or local oscillator and the output is the "RF" port. Keep in mind that the RF and IF ports are bidirectional. They can be used for receiving and transmitting.

See Table 1 for port identification. As shown in Table 1, RF and IF terminals are bidirectional—that is, receive or transmit. Only the LO (local oscillator) terminal is singular in that the LO is maintained for either receive or transmit states. The specific type of mixer you use does not make much difference as long as it will work at the frequency of interest. Most mixers are good to 500 MHz and some to just over 2,000 MHz, then stripline or spe-

Figure 1. Basic double-balanced mixer (DBM) wound on two toroid cores, usually ferrite.

Figure 2. Typical case styles. Style "B," the larger unit, is popular with the SBL and SRA mixer types. Style "C" is typical for TFM types.

cial construction type mixers take over.

10 GHz Mixers/Applications

The easiest mixer for microwave use is the 3 dB hybrid mixer. See Figure 3. This is the mixer that is used on my 10 GHz system. It can be easily reproduced in larger scale for other lower microwave frequencies and is very forgiving of construction errors. The local oscillator injection is on 10.223 MHz and uses an IF frequency of 145 MHz (a 2 meter SSB HT) for receive and transmit.

On the mixer RF port, coaxial relays are used to switch preamp direction to change from receive to transmit. In this way only one low-noise amplifier is needed for normal receive and then it serves as a gain block in the transmit direction to boost the output from the mixer to a higher level. In my application, I use the amplifier to

drive a 10 watt TWT (traveling wave tube) to full output power. A TWT requires about +2 dBm drive power and has about 40 dB gain. For reference: 0 dBm = 1 mW, +20 dBm = 100 mW, +30 dBm = 1W and +40 dBm = 10 watts.

To construct a converter for any frequency, all you need is a mixer and local oscillator source, and an I-F amplifier. The frills for transceiver and filtering can be added later as the converter progresses. All stages in the mythical converter can be individual circuit blocks made up of surplus or salvaged components (gain blocks/mixer blocks) and hooking them together in a coaxial connection. It's really quite easy. If you don't believe this, look inside any high quality spectrum analyzer or microwave test set as this is basically the approach they take.

The same is true in my 10 GHz station. The mixer used was surplus and

a bare-bones 3 dB hybrid type. It was enclosed in a box fashioned out of 1/2"-wide brass strips. Again, SMA coaxial connectors were soldered to the appropriate ports on the PC board for the RF, LO, and IF connections. See Figure 4 for a description of this type of mixer construction. This surplus mixer was intended for use at 12 GHz with an IF of 1.4 GHz. We had to modify the IF port to make it usable at 145 MHz. This was accomplished by cutting dead the 1.4 GHz RFC (stripline) and replacing it with small wire-wound RF chokes resonant at 145 MHz.

Recently, during the ARRL 1992 10 GHz contest, I took this same mixer, using it in my 10 GHz system. Operation on the last weekend was mobile 10 GHz SSB with my partner N6LW. Both of us operated 10 GHz mobile in motion along the coast road from San Diego towards Los Angeles. We used the waveguide slot omni antennas described in this column some time ago. This omnidirectional antenna made mobile operation possible. The omni performed well, giving about 10 dB nominal gain.

How was operation? Well, we both logged about 27 SSB contacts from Kerry N6LW's truck. The

rigs we used were placed in boxes in the bed of the truck and they had to be modified for mobile operation. We had been using toggle switches to transfer relay-controlled circuit functions from receive to transmit.

The circuit was modified by constructing an RF actuated relay circuit that would do the required switching in the 10 GHz converter when we pushed the PTT on our 2 meter HTs in the cab of the truck. In this configuration, the 2 meter HTs act as a rec/xmit IF of our 10 GHz system. When we operated the PTT on the 2 meter HT, RF was detected in the truck bed detect circuit and it in turn operated a myriad of coaxial relays in the rear of the truck. This re-configured our equipment from receive and went to transmit, activating the TWT amplifier last. Quite a hunk of junk going on, but it performed flawlessly for the entire day's operation on both Kerry's and my system.

With the switching in good operation and planing operation using omnidirectional antennas several things had to be proved. As far as I know, mobile operation in motion has not been done before, at least with omnidirectional antennas. In actual use the antennas worked out quite well, as shown by the 27-some contacts we made. Of course, we took advantage of the terrain along the coast highway, making most paths over the water. However, many contacts were made over land paths and communication

Figure 3. 10 GHz surplus hybrid (3 dBm) mixer, not to scale. The actual size is 3/4" square. All elements are constructed with 1/4-wavelength stripline. The IF port has a 1/4-wavelength stub acting as a short to 10 GHz and passing low frequency 2 meter IF.

Camel-Back Beam?

Out in Sudan there are bunches of camels. So I took my rig out with me and hung a 10 meter HalitSquare from poles stuck into the camel's saddle. Everybody laughed. But I had a slew of camel-back QSO's back to the States that way. — What? You don't have a camel for your HalitSquare? So string it from what you've got.

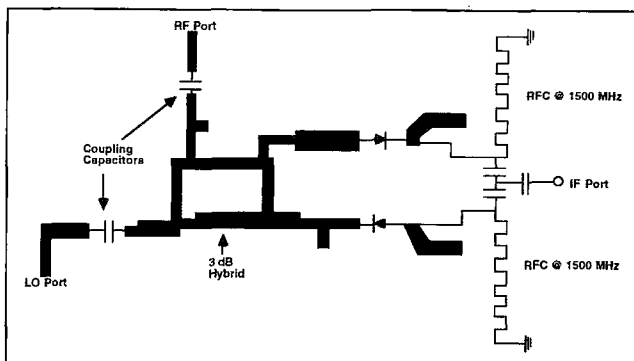

Figure 4. 12 GHz commercial mixer with 1500 MHz IF to modify the IF port for 150 MHz/2 meter IF. Cut out 1.56 GHz RFCs and replace with 2 meter RFC. RFC (choke) must be a miniature device the size of a 1/4-watt resistor as the PC board is 3/4" wide by 2" long.

was just great. When the Doppler shift became too great due to our motion and signals were strong, we shifted to FM narrowband operation with our HTs (a flick of the mode switch). FM worked quite well. As a matter of fact, in a few cases communications on 10 GHz was so good it was a vast improvement over simplex 2 meter communications.

We made no attempt to aim antennas, other than trying to locate a parking space or drive until signals peaked up to higher levels. On one stop temptation was rampant as the best signal strength was obtained when parking in front of a bakery. Normally, traveling from San Diego to Los Angeles is

done on freeways and little is noticed of the small coastal communities. But, since time was not important, we took the coast road and it proved to be an additional pleasure for a Sunday outing.

So much for our operation. The point I wanted to make is that our rigs worked well and they were constructed out of surplus components. You don't have to pay dearly for an expensive commercial unit, just watch the surplus sales and swap meets. What you want may be disguised as part of a much larger PC board. In our case, we had to cut the mixer out of a much larger PC board and attach connectors to it. It worked well. Keep your

eyes open and you too can possibly find some rare goodies in surplus.

International Microwave Operation, Denmark

I received another bit of information from Steen Gruby OZ9GI in Denmark. Steen sent the logs of operation from their group's (the North Zealand and Procom's Amateur Radio Club) activity. They operated on not only 10 GHz but 24 GHz and 47 GHz as well. Quite an accomplishment. In 1990 the best they did on 24 GHz was 227 km, set by OZ1UM and DB6NT, just 52 km off the world record for 24 GHz distance. This year they planned to work 47 GHz and from their notes never believed that they would equal or better their previous distances set on 10 GHz or even 24 GHz. However, DB6NT, DF9LN and DF2CA succeeded in carrying out a two-way SSB/CW QSO with OZ1UM. That equates to a contact on 47 GHz of 90 km, and a European record.

The equipment at DB6NT was a transceiver with 5 mW output and a noise figure of 15 dB. They used a 30

cm parabolic dish with a Cassegrain feed system. OZ1UM's transceiver had 100 microwatts and a similar noise figure, 15 dB. See Photo A. The antenna was a 25 cm Procom dish with an open waveguide feeding system, referred to as a "shepherd's crook." They all appear quite active and look like they are mounting a very serious effort towards breaking the world distance record of 104 km on 47 GHz. I have to add that they must have had a good source for components especially for 24 GHz and 47 GHz materials. Members of our microwave group here in San Diego are looking for materials for these frequencies as they are quite hard to obtain. You have to watch out for lots of those components that start with the "M" word ("microwave") that makes components expensive at swap meets and other gatherings.

Well, watch out for that "M" word. I hope you enjoy it as much as I do. As always, I will be glad to answer any questions concerning this or other related topics. Please enclose an SASE for a prompt reply.

Writing for 73

At least three or four times a week, somebody asks me about writing for 73. Since we are always on the lookout for good articles, for 73 and for our sister publication *Radio Fun*, I thought I'd use this space this month to give you all some pointers on getting published. I hope many of you will give it a try.

What to Write

This is the easy part. Any book on free-lance writing will tell you that the best way to know what kind of articles a particular publication is looking for is to read that publication. Not just one or two issues, either. You want to get intimately familiar with a magazine's style and content, so that means looking at recent back issues (the last year or two) and every new issue as it comes out (writers who use on a regular basis get free subscriptions—newcomers have to earn one). Reading current issues will keep you from writing about something we've already covered recently.

If you read 73 on a regular basis, you know that we mostly publish construction articles, other "how-to" type articles and product reviews. Product reviews are almost always assigned to writers who we've worked with for a while. Every once in awhile a product review will come in for some item that we hadn't thought of. If the product is relevant and the writing is good, we'll buy it. This is probably the toughest way to get published in 73, but it does happen on a regular basis. If you want to try a product review, stay away from the major manufacturers—or at least their main products. The latest 2 meter HTs and HF rigs are *always* reviewed by writers we know (in case you're wondering, yes... we do have to return the items to the manufacturers). Also, stick to products that have been introduced or upgraded within the last year. Things like antennas (especially beams or other "heavy iron"), testbench gear, electronic kits and gadgets from some of the smaller manufacturers are good products to think about. If you've recently bought something that you particularly like, study a few of our recent reviews, then go to it. You can make it as technical as your testbench and knowledge allows, or you can do a more informal "user review" (we publish both kinds, but tend to lean toward the more informal). One word of caution: Do *not* call a manufacturer and try to get a piece of free gear from them by telling them you're "writing for 73." All the manufacturers know (or at least they should) that equipment loaned for review is shipped to our editorial offices before going to the author, and all of our regular reviewers know that they should never call a manufacturer on their own.

The easiest way to get published in 73 is with a good "how-to" article. It could be anything—a construction article, a clever solution to a tough antenna installation, an article about how your club ran a successful membership drive or licensing class. If your article has to do with amateur radio and it shows others how to do something, you've already won half the

David Cassidy N1GPH

battle. The other half is the writing part.

How to Write

While I don't pretend to be the last word on good writing, I have read a lot of books on the subject by those who are. Writing well is not difficult. A few simple rules, if followed, will help anyone with an average education to write acceptable prose.

Rule Number One: Read! If you are not a reader, chances are you are also not much of a writer.

Rule Number Two: Do not try to write about something you are unfamiliar with. An editor can smell BS from across the room, and so can a reader. Write about what you know.

Rule Number Three: Do not use a big word when a small word explains your point just as well.

Rule Number Four: Do not use two words when one word will do.

Rule Number Five: Do not repeat yourself. Make your point, then move on.

Rule Number Six: Your article (story, novel, screenplay) should be exactly as long as it needs to be—not one word longer, not one word shorter.

Rule Number Seven: Get your facts straight. Not close enough. Not "it sounds right." Anything that you present as a fact must be 100%, no exceptions, accurate.

In magazine writing, you need to grab the reader in the first sentence or two. If you don't, he'll move on to the next page. Don't spend the first three paragraphs with a cute story about how you came up with your whiz-bang antenna. Explain the problem, propose the solution then get on with it. Also, don't get overly concerned with style and vocabulary (see Rule Three). Write as if you were writing a letter to a close friend.

One final thing... and this is the absolute most important thing for any new writer to get into his or her head right from the start. Are you ready? Here it is: All good writing is REwriting. Nobody—not your high school writing teacher, not Ernest Hemingway, not Walt Whitman, not Rachel Carson, not John Irving, not Alice Walker, not Stephen King—nobody writes so well that they don't need to rewrite. The first words on paper are just that—words on paper. The craft of writing is taking those words and making them say *exactly* what you want them to say, in the best way you can say it. If you haven't gone through at least two or three rewrites, you're not writing, you're just typing.

Be Nice to Editors

Despite what some professional writers might say, editors *do* have hearts and anything you do to make their job easier will make them all warm and fuzzy inside. The first thing is to reread the above paragraph about rewriting. A good editor (or even a bad one, for that matter) can tell a first draft before opening the envelope. You can't fool us, so don't try.

Other things you can do to make an editor think of you kindly all fall into the "common sense" and "common courtesy" arenas. Get yourself a good book on

Continued on page 72

Jim Gray W1XU

Jim Gray W1XU
210 East Chateau Circle
Payson AZ 85541

As this is being written (mid-November) the solar flux that had been declining steadily for several months has turned around and increased to the 150s during the past three weeks or so, and the higher HF bands have been very good for DX. This happy situation, however, is likely to have returned to normal by the time you read this, and turned downward again. February is *not* expected to be a particularly good month for communications on the HF bands.

Look for a disturbance in the magnetic field on or about February 1st, with possibly very poor band conditions, perhaps even a DX "blackout." There is likely to be an even worse situation surrounding the 10th of February (give or take a day or so) which is likely to last for four or five days. HF bands are likely to be very upset again, and you might even find some very disturbed geophysical conditions, like heavy winter storms, and other effects on earth. Finally, a day or two surrounding the 21st is likely to exhibit very poor HF band conditions once again. Between these times (see chart) you will find Good-to-Fair band conditions—typical of February. On "Good" days there ought to be openings into Europe in the morning, to Africa at midday, and to the Pacific in the afternoon or early evening, on the bands between 20 and 10 meters. Although the higher bands like 10, 12, 15, and 17 meters may close by sunset, 20 meters should stay open until early evening hours. Short-skip will be available on most bands above 30 meters during daylight hours. On 30, 40, and 80/160 meters, you can expect late-afternoon-to-early-evening openings into Europe, with the lower bands becoming better and better as darkness overtakes all of the U.S.A. In the early mornings, expect openings into the Pacific on "Good" days. As always, 160 meters—are at night and poorest during the day because of high absorption of these lower frequencies.

The daily forecast can be followed for times of "Good," "Poor," or "Fair" band conditions. On "Fair" days there will be some propagation east and west, but more likely on north-south paths. On "Poor" days the HF bands

may exhibit polar path echo and garbling, with little or no propagation to Europe or the Pacific. There could be some trans-equatorial communication. There can be abrupt signal drop-out and much fast QSB or fading—even on decent signals. Use the band-time-direction chart to pick the best hours for DX on the various bands, modified by what you see on the daily forecast. WWW is your best friend for current information of Solar Flux and Magnetic Field indexes. Remember, the *higher the Solar Flux and the lower the Boulder K and A indexes, the better conditions will be for worldwide propagation.*

Let me know how these forecasts work out for you, and if more explanation of their use is needed. See you next month. Jim Gray W1XU.

FEEDBACK... FEEDBACK!

It's like being there—right here in our offices! How? Just take advantage of our FEEDBACK card on page 17. You'll notice a feedback number at the beginning of each article and column. We'd like you to rate what you read so that we can print what types of things you like best. And then we will draw one Feedback card each month for a free subscription to 73.

Manuscripts Contributions in the form of manuscripts with drawings and/or photographs are welcome and will be considered for possible publication. We can assume no responsibility for loss or damage to any material. Please enclose a stamped, self-addressed envelope with each submission. Payment for the use of any unsolicited material will be made upon publication. A premium will be paid for accepted articles that have been submitted electronically (CompuServe ppn 70310,775 or MCI Mail "WGEPUB" or Genie address "MAG73") or on disk as an IBM-compatible ASCII file. You can also contact us at the 73 BBS at (603) 924-9343, 300 or 1200 baud, 8 data bits, no parity, one stop bit. All contributions should be directed to the 73 editorial offices. "How to Write for 73" guidelines are available upon request. US citizens must include their Social Security number with submitted manuscripts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by Wayne Green Inc., 70 Route 202 North, Peterborough, New Hampshire 03458. Entire contents ©1992 by Wayne Green Inc. No part of this publication may be reproduced without written permission from the publisher. For Subscription Services, write to: **73 Amateur Radio Today**, P.O. Box 58866, Boulder CO 80322-8866, or call 1-800-289-0388. In CO call 1-303-447-9330. The subscription rate is: one year \$24.97; two years \$39.97. Additional postage for Canada is \$7.00, and for other countries \$19.00 surface and \$37.00 airmail per year. All foreign orders must be accompanied by payment in US funds. Second class postage paid at Peterborough, New Hampshire, and at additional mailing offices. Canadian second class mail registration number 9566. Canadian GST Registration #125393314. Microfilm Edition—University Microfilm, Ann Arbor MI 48106. Postmaster: Send address changes to: **73 Amateur Radio Today**, P.O. Box 58866, Boulder CO 80322-8866.

Contract: By casting your eyes upon this tiny type, you have just legally bound yourself in contract with the publisher of **73 Amateur Radio Today** to go out and show a non-ham how much fun amateur radio is. Take 'em T-hunting, show 'em how to set up a QRP CW station in the woods, let 'em make a few DX contacts, show 'em how to build an antenna, demonstrate packet and satellite communications... there are 101 fabulously fun things to do, and our future depends on newcomers.

NEVER SAY DIE

Wayne Green W2NSD/1

Another Bummer

A letter from KH6COY mentioned the military being a supporter of amateur radio as a way to preserve frequencies for their use in time of war. Yep, that was one of the unstated benefits of amateur radio back when I was a whipper-snapper . . . back when I still had more hair on my head than on my chest. Well, both war and technology have changed so, far's I can see, this is just another relic of the past.

Sure, when WWII came along and we got whopped at Pearl Harbor, we had to start almost from scratch and build an army and navy, complete with communications. Lordy, when I reported aboard my submarine in 1943 one of the two radios we depended on was still a 1920s-vintage TRF set. That's right, from before the super-heterodyne! And when I worked for a few months for G.E. in Schenectady (before joining the Navy) making portable transmitters for the Army, the design had been finalized in 1935. I couldn't believe how out-of-date the stuff was we were building. Apparently no one had made any plans for pursuing a war, so they had to go with whatever they'd been making several years earlier.

Roosevelt quivered with rage when the Japanese bombed Pearl Harbor. His rage should have been with his intelligence people and our military for being asleep, not the Japanese, who did exactly the right thing. They knocked us for a loop and quickly spread out all through key areas of Asia. The Japanese high command wanted to stop us up front, grab a bunch of badly wanted territory, and then sign a peace treaty which would let them hold everything they'd conquered. They misjudged our dudgeon. We then went ahead and gradually out-invented them in radar, out-produced them in weapons, and ground them down. The atomic bomb was just the capping high-tech blow.

In those days we needed the ham bands for military communications. Of course we had a couple years in which to invent and build our electronics and communications systems. War is completely different now. The Persian Gulf war lasted a few days, not four years. Communications systems for war use these days have to be integrated into weapons systems. They have to have been in operation for a long time so the bugs will have been worked out. Whatever radio frequen-

cies the military need today for any wars we can imagine are already in full use.

The military are in no more need of a bunch of ham bands than they are of a bunch of fat old men to draft as operators. In the 1940s our average age was in the low 30s, with 80% of all new hams being teenagers. This is why 80% of all licensed hams were drafted into the military during WWII. And we did indeed make a big difference. I joined the Navy in 1942 and breezed through their electronics school in nine months, emerging as a radio, radar and sonar expert. I had the option of working in a research lab in Washington or going to sea. I chose submarines and as a result had a bunch of exciting adventures.

Today's communications equipment is completely packaged. The frequencies are built in, complete with the security systems. We don't need operators to copy CW anymore. We don't even need technicians to repair broken equipment in the field. If it breaks, a module is substituted or else the whole unit is replaced. How many hams do you know who service their solid-state synthesized rigs when they go blooey? We send 'em back for factory service.

The military have no use these days for hams for anything. They don't even need our bands anymore.

There's a great controversy over what role our military should be geared to play in the future. Are we going to let our media suck us into one adventure after another on the basis of our heart strings being pulled? Is this what we want to spend

a good part of our tax money doing?

We're in Somalia now. The pressure is on to get into the Serbian mess. Hussein and the Kurds are at it again. Then we'll be worrying about the extermination of zillions in southern Sudan. And further killing in Ethiopia. We're already faced with a growing interest by Muslim fundamentalists in killing us infidels in around 50 countries. I loved it when the Somalis we were trying to save from starvation stoned us for being Christians. Our media can have a ball getting us involved in endless messes. Maybe we should go into India and pacify the Muslims and Hindus, who've been killing each other for generations. How about the terrible mess in Burma, which I've visited and seen first hand? And the genocide in Timor? Sri Lanka? Chad? What about the native Fijians who want to kill the Indians? The Azerbaijanians want to kill the Armenians and vice versa. How soon can we get Tom Brokaw into the breach?

Now that we've beat communism, all that's left is to whip the rest of the world into submission. But the one thing we're not going to need is any of our ham bands.

What's Cooking?

If you want to live to be 70 and take advantage of the free skiing us septuagenarians enjoy, not to mention getting those full Social Security payments, even if you're still working, you're going to want to have stopped smoking early on, taken it easy on the beer, and kept your weight down. The next time you're wandering around at the Dayton Hamvention, just take a

look at how many tons of hamfat you see waddling around. Tsk.

There are plenty of great things you can cook which will help keep your weight down, things which you can whip up in minutes. For instance, there's Uncle Wayne's Onion Slumgullion, which I guarantee you'll love. And it only takes maybe 10 minutes from start to finish.

You dice up a 3" onion, slice a quarter cabbage into quarter-inch strips, quarter a 1" chunk of Polish Kielbasa and then cut the quarters into 1/8" slices. You're almost done. You put all this into a large frying pan with some bacon fat to keep it from sticking, turning it to prevent burning.

While that's cooking, bring two cups of water to a boil in a small saucepan. Add a crunched up package of ramen noodles and cook for three minutes. Strain the noodles to get rid of the water and add the little package of flavoring. By now your onion and cabbage mix should be done. Turn off the fire, mix in the noodles and serve.

I add salt while I'm cooking, plus plenty of black pepper. You can try it bland, but then give it a try with a heavy pepper hand. Vegetarians can leave out the pieces of sausage. The above makes enough to feed two for a fast dinner. I often make up a double portion and put the leftovers into the fridge to be warmed up in the microwave oven. Tastes like fresh-made.

If you haven't been provident enough to make some homemade applesauce to go with the Onion Slumgullion, you can make some in about five minutes. Allow one medium apple per person and slice into a microwave dish, skin and all. You want to start with a tart apple, like a Baldwin, Cortland, Macintosh, Northern Spy, Transparent, or Duchess, and *not* one of those crummy bland Delicious. Quarter the apple, cut out the core (a grapefruit knife does this well), cut the quarters into four chunks so they'll cook fast. Add a handful of raisins, a couple tablespoons of Brownulated sugar and a half inch of water. Cook about three minutes in the microwave and you'll have a great companion for the Onion Slumgullion.

It's been awhile since I've given the recipe for Uncle Wayne's Hurry Curry, so keep after me and I'll write it up again. It's fast, fabulous, and diet food. Of course, if all you've ever learned to eat is hamburgers, then I can tell you how to make the best hamburger you've ever tasted, and fast too. I enjoy cooking, but I like things I can fix in a few minutes. Ask me about Uncle Green's Beans.

One more thing—how about a low calorie dessert? My favorite is sugar-free Jello with a bunch of fruit in it. The only calories are in the fruit. I prefer to use two large packages of orange Jello (130 calories) and mix in a can of water-packed sour cherries (save the juice, it's delicious to drink), a can of crushed pineapple, and a can of free-stone peaches (cut into chunks). This make about four quarts of fruit Jello, which lasts me a couple weeks, a nice low-calorie dessert, even when served with a teaspoon of light cream on it.

Hmm, this is making me hungry.

QSL of the Month To enter your QSL, mail it in an envelope to 73, Wayne Green Inc., 70 Route 202-N, Peterborough, NH 03458. Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to 73. Entries not in envelopes cannot be accepted.

From The Hamshack

Michael A. Moore N7RY, Estacada OR Wayne, I see you are searching for comments on the "Dream Station" (November 1992 issue) and I can't resist making a comment or two. For my money, the ICOM 765 transceiver would make a real start on your station. It runs AM/SSB/CW/FSK with over 100 watts out and stays cool doing it. It has quite a few switches and buttons, though fewer than some other current HF offerings, and most of them you can happily ignore. I am not sure if you run much RTTY these days, but if you were going to, the "real" FSK done with a digital synthesizer is light-years ahead of feeding audio to the SSB input.

Now CLOVER is coming out, and we will be back to audio tones into the SSB again, but the 765 is about as clean on SSB as you can find, so it would handle it. It has a nice speech compressor that is clean for SSB as well. Let's not leave out CW—it runs full break-in and has a built-in iambic keyer. You just plug your Bencher or whatever in and you're set.

I have run RTTY and CW contests with the 765, and if I had more time/better antennas I think I could get some real wallpaper!

There are times when 100 watts won't do, so I guess one should have a decent amplifier. I personally like amplifiers that are suited for RTTY use; too few are these days. May I recommend the Ten-Tec Titan or Bill Henry's 3K? (I know Dick Ehrhorn's devices are solidly built but at last glance his units were priced a bit higher.) The Titan will handle key-down RTTY for contesting, and is probably overkill for SSB and CW, but I hate smelling/inhaling smoke in my shack, and I assume you value your lungs equally highly.

My favorite amplifier is a homebrew pair of 4-400s that my father Art K8LXF and I put together 30 years ago, with a huge plate transformer and silver-plated coils, the latter mostly for looks. It has 3/8" solid silver contacts on the coil switches, and has lasted many hours of RTTY FSK. If I cannot work a station with that, it is seldom worth turning the Titan on to try any further until propagation shifts.

Towers are another hassle. The easiest to put up these days are the aluminum towers by Glen Martin Engineering, with a HAZER trolley on them. I use his trolley on 50 feet of Rohn 25G to play with different antennas. If money were no object, the Telrex steel poles that turn would be the ticket for the lower part of the sunspot cycle coming up, but that is not in keeping with Yankee frugality.

Of course, if you want to be up 100 feet or so, it is best to stick with guyed Rohn 45G. (Ken K6SAD has put up 120 feet of 45G by his lone-

some self, which I don't advise but offer by way of astonishment.)

I have heard good reports from the KLM beams, but stacked Hy-Gains or Mosleys will outdo even those. If your locale has high winds, as we do here, I favor Telrex beams as they will take ice-rains that thicken the elements several inches without falling in the wind/rain.

Don't forget a quad of phased verticals (or at least one vertical) for the low bands—40, 80 and 160m will have some good times ahead. I have heard some of the more interesting rag-chews on 160m in recent times.

Enough soapboxing; keep up the good fight, and tell it like you see it. Amateur radio needs a dose of Green jalapeños from time to time.

Chuck Reik N8WDH, Garden City MI I would like to comment on the article by John Rehak N6HI reviewing iambic keyer paddles, which appeared in the December 1992 issue of 73. I found this article to be extremely interesting and informative.

I would like to offer a suggestion that would be of benefit to those of us who are aficionados of the straight key: Perhaps a similar article might be possible. I have no idea what percentage of your readership is of the same bent as I, but I would think that there must be a few of us. Apparently, there are enough of us to warrant making straight keys in quite a variety.

Walter E. Taylor K4VI, Charlottesville VA Wayne, I just read your NSD column in the December 1992 issue of 73 Magazine.

Your remarks about the rainfall in Ketchikan, Alaska, prompted this reply to you. You were not even close to giving the correct value of the amount of rainfall in other places of the world and the US. Look up the weather records for the interior of Kauai in the Hawaiian Islands. They have averaged over 500 inches of rain a year for many decades. There is a rain forest in India/Pakistan that averages more than 530 inches a year. Both of these places make Ketchikan seem like a desert.

Morris Bleckman N9GVA, Lincolnwood IL I just received my January 1993 issue of 73 and I think you have forgotten me. I am not a builder of radio equipment, I am an operator. I admit I got into ham radio about five years ago without any background in electronics. At this time I operate my ICOM 751A, complete with a 55-foot tube tower (I dug the hole and poured the concrete) and a KT34a tribander, plus a G5RV and an R7 vertical after the HF6V blew down in an ice storm. I also have a 735 on my 40-foot sailboat. All of this was installed by yours truly. And it all works. I even know

what end of an iron gets hot BUT I don't build. I welcome articles that discuss problems of equipment and the uses of same.

Again, I am an operator and user of equipment. I want to know more about the uses of test equipment and how to use it. I want to hear about the pros and cons of equipment. I want to know about the differences and how to use them to my advantage. Gordon West WB6NOA was of great help when I installed a 735 in my boat. I phoned Mr. West on a couple of occasions with a tech question concerning mobile installation and he was always helpful. Ditto for Bob Hell about his speakers. Got the idea? I am not into schematics.

Wayne, I enjoy your editorials. I, too, am a WWII USNR type, from 12/07/41 to 12/18/45, most of it as a photomate 1st Class with flight pay in an interpretation outfit. I, too, was a newsreel cameraman for CBS station WBBM TV, and I, too, left the camera and with a partner ended up with the largest 16 mm film processing lab in Chicago. When I sold it to my employees, it was 100% video.

There isn't any way I am going to send \$ for your ranting and raving. YOU ARE SUFFERING FROM TERMINAL SANITY. I know the symptoms.

Morris—I agree! I'd love to see more articles on the topics you describe. In fact, why don't you take a crack at writing some!

As for the charge of running so many construction articles, we plead guilty as charged. Our reader feedback cards always, without exception, list construction articles as the number one topic our readers would like to see more of—and we already publish twice what the other ham magazines do . . . David N1GPH

William A. Scherr, Jericho VT Wayne, I thought your piece on RF health hazards was simplistic while trying not to seem so. I use a window mount, Radio Shack telescoping or field-expedient antenna to transmit. I'm still waiting for my ticket, but I am an RTO for my National Guard unit. They told me all about RF radiation in Basic. Short rubber duckies aren't any good, period.

I enjoyed the piece on the micro-mag antenna, but my XYL still won't let me put one on her jeep.

I like your attitude; keep it up.

Arnold Samuels KH6COY, Ocean Shores WA Wayne, while I agree with you 99.999% of the time, I must take exception with you on something. Oh, I know we can't teach the old farts anything new. I do feel, however, that we have to make a start to teach the new generation of hams that ham radio is not an entitlement program. I know we have lost our value to society, but it doesn't have to be that way. I also know that you are aware of the fact that if it were not for the military needing these frequencies in case of an emergency and considering our

bands as a contingency we would have lost them a long time ago. I used to sit on CINCPAC's frequency coordinating committee in Honolulu back in the '60s and I know what's in their minds.

I am an old Stuyvesant graduate, and we had a ham station (WB2CLE). I went back for a reunion last June. Yes, you guessed it—no more ham station. It is sad how ham radio has gone down, just like the rest of our educational system. When I started with the Voice of America, about 90% of the engineers were hams. We all had to have 1st class licenses, etc. Not anymore. You are right—ham radio went downhill with incentive licensing. Do you think we can ever turn this thing around?

Now something for 73's readers. I just completed computerizing all my old logbooks. What a job! I operated from Wake Island from 1962 to 1966 as KH6COY and KW6DS. I still have a handful of KW6DS cards. If there are any collectors out there who made contact with me and need a card I would gladly oblige if I can verify it. Send a self-addressed, stamped envelope.

T. C., Victoria, Australia As an avid reader of your magazine, I certainly enjoy the up-to-date articles you have. Apart from being economical to build and in the original spirit of build-it-yourself amateur radio, they are also of great educational value. I only wish your distributors did an even better job as I seem to have recent difficulties in receiving my copies. One further problem is that you guys seem to take a long time to get things right—two corrections to the PMP and still mistakes.

One tip to PMP builders which I discovered the hard way was the way pins 6 and 8 were tied together on the original circuit board. It won't work! Pin 6 on the TCM chip has a divided clock output which stops pin 8 from talking to the computer. My suggestion is that you guys ought to set up a lab of your own like the ARRL and duplicate circuits submitted to filter out potential errors like this. You would make life a lot easier for your readers.

Anyway, after all this grumble, as my subscription is due in July 1993, I wonder if you would be so kind as to reward my loyalty with a year's free subscription. After all, our diminishing currency versus yours is gradually making your journal out of reach.

T. C.—We're currently negotiating with a new distributor in your part of the world, so hopefully things will get better soon.

Thanks for the corrections to PMP. We're a small outfit here and we simply can't afford the expense of a testing lab. We rely on our authors to make sure their stuff is clean, and we rely on our readers to tell us when we screw up.

Nice try on the free subscription. Unsuccessful try, but nice . . . David N1GPH.

Packet Radio Equipment Needed for Poland Center

Packet radio equipment is needed for "Community-Based Computer Centers" in Poland. The first center was opened recently with a network of five new computers, two printers, a fax/modem, and other peripherals, through the efforts of the American Council for Polish Culture (ACPC) and the support of the Institute for Community-Based Computing (ICBC) of New Durham, New Hampshire. The center, located in Siedlce, an economically depressed region of Poland, is opening up opportunities for young adults, including the disabled, to study and work with state-of-the-art computer equipment and key programs, particularly desktop publishing. While all of the equipment installed at the center has been donated or purchased through the ACPC and ICBC, the community itself is providing the space, utilities and manpower to operate and maintain the center. During 1993, the ACPC and ICBC plan to replicate the Siedlce center in three other communities in Poland.

The U.S. State Department has suggested that the center training opportunities and operations could be further enhanced by improved communications with other parts of the country through the introduction of packet operations. The ACPC, a 501(c)(3) nonprofit organization, is appealing for donations of packet radio components (radios, controllers, antennas, etc.), new or used, for the installation of one complete unit at the Siedlce Center and a unit in each of the three additional centers planned for 1993. Anyone interested in helping by donating equipment is requested to contact: Mr. Marion Winters, ACPC Computers for Poland Project Director, 953 Wellington Road, Rindge NH 03461; telephone (603) 899-6333.

FCC Issues 222 MHz and 23 Cm Proposal

The FCC has proposed several changes in the 222 and 1240 MHz amateur bands. The first would establish a small new subband in the 222 MHz band where repeater stations would be prohibited, in order to enhance weak-signal communications and experimentation.

The second proposal would allow Novice class licensees access to the entire 222-225 MHz amateur band.

The third proposal would allow Novice class operators to be licensees and control operators of repeaters in the 222-225 MHz band and in the 1270-1295 MHz Novice subband of the 1240-1300 MHz band.

The "weak signal" proposal was made by the ARRL in November 1991, following the reassignment of 220-222 MHz to commercial interests. The League suggested a 150 kHz subband at 222.00-222.15 MHz for such weak signal work.

The ARRL at that time also requested expansion of Novice operating privileges to include the entire 222 MHz band, in order to establish a common meeting ground where Novices could sample other modes of amateur operation in addition to repeaters.

The proposed changes in Novice repeater license and control operator privileges, which the ARRL did not seek, came as the result of petitioner Michael C. Trahos KB4PGC, who argued that the Amateur Service should follow the General Mobile Radio Service and the Private Land Mobile Radio Services, where user licensees may also be licensees of repeaters without being required to pass any additional examination. The ARRL has not as yet adopted a position on this proposal.

The Commission said it believed there was merit in the petitions of both the ARRL and Trahos, and has asked for comments on the proposed rule changes in P.R. Docket 92-289. No deadline has as yet been set for those comments. *TNX ARRL; Westlink Report #640, December 24, 1992.*

Rescue at Sea

An Illinois ham operator helped to rescue a pair of British yachtsman trapped in a floundering sailboat sinking some five hundred miles off the Florida coast. Former Air Force radio technician Wilbur Warke N9RGE heard the distress call from the sailboat *Que Tal* while killing time before leaving for work on December 7, 1992.

According to Warke, he was monitoring the bands when he happened across a voice with an English accent asking for emergency assistance. Warke was able to get a location on the sinking boat. He relayed that to the Coast Guard, which in turn arranged for the Norwegian tanker *Team Trinta* to go to the sailors' aid.

Shortly before 4:00 p.m. local time, the Coast Guard called back to Warke to let him know that the tanker had the *Que Tal* in sight. A short while later the sailors were rescued and taken on board the *Team Trinta* just before the *Que Tal* sank. The two English sailors were identified as Nicholas Kyriacou and John Briffa. They had set sail from North Carolina on November 2nd with their destination being Aruba. *TNX AAØCR; Associated Press; ARRL; Westlink Report #640, December 24, 1992.*

QCWA Scholars Awarded \$7,200 in Nine Memorial Scholarships

Nine 1992 QCWA scholarships—totaling \$7,200—have been awarded to students from nine different states. (Applications were received from 49 states this year!)

These educational grants are made each year from interest earned on the QCWA Scholarship Fund, established in memory of their Silent Keys. A total of 14 \$800 scholarships will be awarded in 1993.

This year's winners are:

Melissa L. Benish N3FAC, Pittston, PA, will be a junior at Penn State, studying mechanical engineering;

Elena Doerrie KB5DAK, Booker, TX, will be a freshman at Johnson Whales University, studying public relations;

Lesley Goh KD4IPS, Somerville, MA, in her final year working towards a BS degree in computer engineering at the University of Florida;

Martin H. Gruen KA2VLD, Margate, FL, a junior at Stetson University, majoring in biology;

Dustin W. Howell N5ZVY, Minden, LA, studying for two degrees—first a BS in aviation science, then an Associate degree in criminal justice;

Shelly L. Jones KE5DX, Harrison, AR, will be a senior at Southwest Missouri State University, majoring in mathematics;

Rebecca Schoenberg, South Toms River, NJ, plans to major in Biology at Tufts University.

ARRL Files on Proposed Business Rules Change

The ARRL has filed formal reply comments to support an FCC proposal to revise the rules on permissible communications by amateurs. The League said that other commenters seeking fine-tuning of the new rules were asking for an unnecessary rigidity in amateur rules. But the ARRL argued against a request by commercial interests to relax the restriction on the use of amateur radio in ordinary news gathering—a request the Commission had previously denied.

The League had informally submitted a proposal for a change in the rules to the Commission on January 6th, 1992, a change that would restate certain sections of Part 97.113 in order to enable amateurs to continue, unfettered, to perform public service work. The League had not submitted a formal proposal for rule making in the matter. The FCC in April assigned the proposal RM-7895, in P.R. Docket 92-136.

In its reply comments filed December 1st, the League said that trying to be specific in a "content regulation" such as Section 97.113 was impossible. Yet the League agreed that some regulatory guidance would be needed. For example, in the case of amateurs providing communications for events held on a regular basis, the League suggested that weekly events should be considered "regular" and therefore not suitable for amateur support. Yet, annual events would be held seldom enough that amateurs could be the best providers of communications.

The League noted that the National Association of Broadcasters (NAB) and the Radio-Television News Director's Association (RTNDA) were jointly seeking once again to relax the restrictions against the use of amateur radio in day-to-day news gathering, despite having been twice turned down by the Commission on that very subject. The League cited comments from an NAB member and former RTNDA board member who called the plan "self-serving" on the part of the broadcasters and pointed out dangers in amateurs being used regularly as news gatherers.

The League requested that the FCC finalize its proposed restated rule as soon as possible. *TNX Westlink Report #640, December 24, 1992.*

Constructing High Current Power Supplies

Practical considerations, learned through experience.

by David A. Nordquest KE9ED

Much amateur equipment requires out-board DC, so the most useful accessory in the ham shack is probably the regulated, high current 13.8 volt power supply. In building such supplies, back issues of ham magazines, handbooks, manufacturers' data books, and technically-minded friends can give valuable assistance. Unfortunately, some things have to be learned—or relearned—in the laboratory of the School of Hard Knocks. Here are a few of the practical lessons I learned while building a 30 amp, 723-based supply.

Transformers

Transformers take up the most room in linear supplies, and they differ greatly in shape and size, so your whole layout should be planned around one. Selecting a unit can be a problem. Most hamfest specials appear to be unmarked. If you can determine the open circuit voltage, choose a unit whose voltage rating is about 25% to 33% higher than your desired figure under load. This is a rough approximation only; the proper value will depend on the construction of the transformer.

The handbooks give formulas for estimating transformer current capacity from the cross-sectional area of the windings. A very rough estimate can also be made by observing the wire size. Still, I learned that it is a good idea to put a load on unmarked transformers before going too far in the construction. The sag from a no-load to a load condition varies greatly. I had to abandon my first construction attempt because an old battery charger transformer slumped too much. Unfortunately, my new transformer turned out to be too large for the old chassis.

To check for capacity and voltage sag, I loaded transformers with various high wattage, low ohmage resistors. By taking current and voltage readings for different loads I was able to plot enough points on a transformer load line to estimate the hypothetical short circuit current at zero voltage. A transformer is probably good for 10% or 15% of the estimated zero voltage current. Luckily, my final transformer, a Basler, came with the manufacturer's test report.

Just what voltage is needed at the transformer's secondary depends on many fac-

tors: on whether a half-wave, full-wave, or bridge circuit is used; on filter capacitor size; on drops in the rectifiers, pass transistors (about a volt each) and emitter resistors; and on the sag in the transformer. A lower voltage secondary can be used if a separate winding (as in commercial supplies) or a separate small transformer (more practical for the amateur) is used to provide the extra 3 or 4 volts of elbowroom the regulator chip needs. This will save on heat dissipation in the pass transistors. Although my transformer has an output high enough for the regulator, I breadboarded the separate trans-

mary windings, one of which had taps for input voltages from 100 to 127. Putting the 0-to-100 volt portion of winding one in series with the untapped 110 volt second winding brought me very close to the output I wanted, but just a bit low. Using that part of the first winding between the 100 and 127 volt taps in series with winding two took the transformer output to 19 volts, which rose to 26 or so after the filter, with no load. That was a bit high, but still quite acceptable.

I was pleasantly surprised by the versatility of transformers with dual primaries and multiple taps. For example, if I want to change my 13.8 volt supply to 24 or 28 volts, I can simply reconnect the AC input to the proper transformer primary taps and adjust the regulator pot. (This assumes that other components are suitably rated.) I picked up two smaller units like this for future projects, because they're so useful.

Construction

Once I found my transformer I looked for a larger case. Eventually I cut down one from an obsolete piece of test equipment and replaced the front panels with thick, double-sided circuit board material. Because the frames of some of these cases are drilled and tapped, it is very easy to remove panels for servicing, meter adjustments, etc. The heavy plastic end pieces on this particular chassis provided a convenient location for mounting the pass transistor heat sink. Since the whole heat sink is insulated from ground, the transistors require no mica insulators, which simplifies mounting and slightly improves heat conduction.

I used some surplus GE 100 or 125 amp diodes to construct my full-wave bridge. Unless you get two diodes with reversed anodes and cathodes, be prepared to saw heat-sink material and to insulate the three required rectifier heat sinks (two single and one double) from each other, as well as from the chassis. If the proper mounting hardware is available all the diodes can be insulated and installed on a single heat sink, but a bridge module is an easier solution. I recently saw a 100 amp model at a hamfest for \$4, new.

It is a good idea to put bypass capacitors

former technique and it worked well.

After my first transformer failed to pass muster or supply sufficient current, a friend's donation of a beautiful new 24 volt 32 amp model brought new puzzles. At the output of the filter the voltage rose to about 34 volts, which was too high for the filter caps I had then and for the number of pass transistors I wanted to use. I considered using another transformer to buck the voltage, but found the amount of iron required to be excessive. I experimented with the two pri-

across the diodes when installing your rectifiers. After my supply was up and running I noticed a strange buzzing noise on an AM radio when I turned the supply on. Holding a capacitor across one diode (carefully!) reduced the noise. Bypassing them all with 0.01 μF ceramic disc caps made the noise vanish. Do this first—that's easier!

Computer-grade filter capacitors are very expensive new, but are readily available for a dollar or two each at hamfests. I eventually found two 67,000 μF , 75 volt units for my supply. The handbooks have formulas for calculating the capacitance needed, according to transformer voltage, voltage and current needed by the load, and type of rectifier used. The 2,000 μF per amp value sometimes recommended as a starting point is only a rough guess. My 134,000 μF value is high, but my diodes are husky enough to withstand the tremendous surges during the microseconds of each cycle when their output voltage is higher than the capacitors—the only time they can conduct.

For the regulator circuit, I chose the 723 chip for its excellent regulation, current limiting, and remote sense capability. Many designs have been published for this chip, but a couple of my "experiences" (the name we give to our mistakes) may be of interest. Avoid too much gain or too little gain in the drivers between the regulator and the pass transistors. Too little gain will make the 723 over-exert itself; too much may make the circuit highly sensitive and subject to microphonics. Initially, I had the 723 driving a 2N5339, which drove a high-gain MJ4035 Darlington, which drove the pass transistors. The drive current from the 723 was so low it was almost unreadable and the supply output was jittery. Eliminating the 2N5339 solved the problem and the 723 still loafed along with a drive current of 100 microamps at a 2 amp supply output. To ensure stability, I put a 2.7k resistor between the 723 output and ground to maintain a more reasonable and constant load.

Builders who want to avoid the hassle of making their own regulator board may want to try a trick suggested to me by Rick WA3MKT. You can purchase a relatively inexpensive low current, 723-based supply

with remote sensing and use the output to drive your pass transistors. If you hook the remote sensing terminals to the main supply output, the small supply will regulate the main one. Although I did not use this technique in my supply, I breadboarded it and it worked well.

If you make your own regulator board, be sure to include a good ground and to run both ends of the divider network (which sets the voltage output) directly to the supply output terminals or to the load. I did not do either at first and my regulation was poor at higher current levels.

Some references emphasize the desirability of using pass transistors of the same designation and lot number. I obtained several 2N3771s, which are much huskier than 2N3055s, and took care to select all from the same lot. I found the gains varied from the mid-teens to about a hundred. Perhaps different lot numbers or even just similar transistors (such as 2N3771s and 2N3772s) with closer gain figures would be as good or better. If you use mixed transistors you will have to design based on the weakest specs. However, gain differences within types are relatively unimportant because they can be swamped by using 0.1 ohm emitter balancing resistors.

Whatever pass transistors are used, their ratings mean little unless they are cooled by an adequate heat sink. Calculating the surface area needed is not at all simple, as the formulas in the handbooks and regulator data books will show. Because amateur-built supplies, like mine, will likely use non-custom transformers, the pass transistors will probably have much more heat to dissipate than in commercial supplies. The number or capacity of the pass transistors and the size of the heat sink should be correspondingly greater than in such commercial units.

Wiring high current supplies is no trivial matter. To avoid unwanted voltage drops, I used two runs of #10 stranded wire, purchased from an electrical supply company, for all heavy current runs. The great advantage of using stranded wire is that it bends more easily, but it is also more difficult to solder to terminal lugs. I took care of that problem by making liberal use of crimp-on

ring terminals, which I soldered to the wires for safety.

Some of my terminal lugs had several wires running to them. The positive output jack had two heavy wires from the current limit resistor, one wire from the regulator voltage-setting divider, one from the over-voltage protection circuit, one from the output capacitor, and one from the voltage meter. It would be difficult to solder all those wires properly to the output jack. I terminated them all with ring terminals and made a heavy copper extension for the jack, with a machine screw attached to accept half of the wires. Where I needed wires insulated from each other I used machine screws isolated by bare circuit board material.

With the heavy wire runs I used and with a substantial current resistor already breaking the positive output path, I had no desire to add another break for an amp meter shunt resistor. Instead, I configured a meter as a 1 volt voltmeter and had it read the voltage across the current limit resistor already in place. By playing around with values I was able to get the voltage figure indicated on the meter to correspond to the actual output current. Because the current limit resistor is so low in value (about 0.025 ohms in this supply) the connection between the meter leads and the resistor terminals should be flawless. When mine was not, I read 4 to 8 amps, rather than the 2 a car taillight was actually drawing. Concerning the output voltage meter, almost any sensitivity will do, if the proper series resistance is calculated.

The relatively simple schematics for regulated, high-current supplies may make them appear like easy and inexpensive weekend projects. Inexpensive they can be, with good shopping and the help of good friends. However, when you add in the tuition charges in the School of Hard Knocks, the opportunity costs do not look so trivial. Nor are home-built supplies likely to be as efficient as commercial units unless a custom transformer is available. Still, I've ended up with an excellent supply and will find my next supply project, and any needed repairs, much easier now—especially if some other alumni of the School will report some of the lessons they had to learn.

Fiber Optics and Amateur Radio

Is fiber-optic technology in our future?

by Roald Steen AJØN/LA6US

Fiber optics is a segment of the communications industry which is evolving rapidly. While fiber optics is used chiefly for land and undersea communications cables, there are also uses for this technology in amateur radio.

One of the most interesting applications of fiber optics in amateur radio may be as a substitute for coaxial cables. As you know, coaxial cables are lossy. The longer the coaxial cable and the higher the operating frequency, the more the signal will be attenuated in a coaxial cable. The falling cost of fiber-optic receivers and transmitters makes fiber optics an attractive substitute for coaxial cables.

We are used to having the receiver and the transmitter in the shack, but the correct location for these devices is really right next to the antenna. Through fiber optics, it is possible to select these favorable locations for the transmitter and the receiver.

The equipment in your shack could produce both the frequency and the modulation of the signal which you are transmitting. Once these two components of your signal are generated in the shack, they can be fed from a fiber-optic transmitter through a fiber-optic cable to the antenna, where an RF amplifier could be mounted in a weatherproof enclosure.

Both the fiber and the electric power to the transmitter must run up to the antenna. This can be achieved, in the case of a solid-state transmitter, simply by supplying the 12 volts DC, needed to operate the transmitter, through low voltage wiring.

Also, for the receiver front end, the best location is as close to the antenna as possible in order to avoid attenuation of the received signal and pickup of noise. Coaxial

cables pick up some electronic noise. By running fiber-optic cable from the receiver front end to the receiver in your shack you eliminate all pickup of electromagnetic

been adopted by some mobile amateur radio manufacturers. Aviation and marine radio manufacturers are also adopting the fiber-optic cable as a link between the control head and the transceiver.

Fiber-optic cables can be used for a number of other control and communications purposes. For example, fiber-optic cables may be used to connect one or several remote receivers to a repeater.

A significant advantage of fiber optics over other communications cables is its enormous bandwidth. A bandwidth of gigacycles is possible. This bandwidth limitation is not a limitation inherent in the fiber itself, but rather in the input and output devices, i.e. the optic receivers and transmitters.

The technology of fiber-optic receivers and transmitters is steadily improving. Scientists working for a Japanese company recently fed information at a rate of 20 gigacycles through a fiber-optic cable exceeding 600 miles. This equals a capacity of around 3,000 television channels. Commercial devices are lacking such laboratory records, yet the capabilities of modern commercial fiber-optic systems can be impressive.

Photo A. Fiber optics is a rapidly evolving communications technology which is of interest to the amateur radio community.

noise in the feedline. Fiber-optic cables are completely immune to electromagnetic noise. You can run a fiber-optic cable right next to the most powerful RF devices without any RF getting into the signal propagating through the cable.

Mobile Radios

Manufacturers of mobile radios have started to embrace fiber optics. Some mobile radios now come with a small but advanced control head which communicates with the transceiver in the trunk through a fiber-optic cable. This technology has also

Optic Fiber Types

There are three main types of optic fibers. Plastic fibers have high attenuation ratings which limit this fiber type to cables that cover up to a few hundred feet. But plastic fibers are cheap and easy to install, and are therefore an attractive material for short cable runs.

Regular glass fibers have some spreading of the signal, since internal reflections from the edges of the fiber ensure that a signal which is sent from one end is received somewhat smeared out in the other end. This smearing limits the amount of infor-

Photo B. A fiber-optic connector. New and easy-to-use fiber-optic connectors with low attenuation are on the market.

mation which can be transmitted. The problem of smearing is especially significant for long cable runs and for circuits that communicate very large amounts of information. This type of fiber, which is the simplest type of glass fiber, is called multi-mode fiber.

A single-mode fiber is an advanced optic fiber. This type of fiber is used in most long-distance fiber circuits. A single-mode fiber has a construction which keeps the light centered in the middle of the fiber throughout the trip, thereby eliminating the problem of smearing.

Connectors have been one of the challenges of the fiber-optics industry. Early fiber-optic connectors were difficult to install and introduced a considerable amount of attenuation in the circuit. However, many large corporations are now competing in the fiber-optic connector market. Connectors have been developed (partly due to the intense competition) that are easy to install and have very little attenuation compared with early fiber-optic connectors.

Modern high speed computing, called supercomputing, would not have reached its present capabilities without fiber-optic communications between computers, control devices and memory devices.

A fiber-optic cable can carry many more television channels than a coaxial cable. Therefore, more and more cable television systems are adopting the use of fiber-optic cables. In cable television systems the optic fibers are used mostly to connect the studio with distribution amplifiers and similar devices. Relatively few homes have been connected directly to optic fibers for cable television.

But it is likely that more and more homes will be connected directly to optic fibers. Not only may the optic fiber bring television into the home, but also telephone service. The technology exists to allow the same fiber-optic cable to be used for both

telephone and for cable television service.

A drawback to telephone service through optic fibers is that the optic fiber cannot bring power to the telephone, unlike a copper telephone wire which serves both as a communications cable and as a power cable for the telephone. The optic fiber must therefore be complemented by copper wires in order to supply the telephone with power. Already, most cables that are laid between telephone switching offices are made with optic fibers instead of copper.

Fiber optics has almost completely taken over for copper in new undersea cables. Currently, there are three transatlantic fiber-optic cables in operation, with a total capacity equivalent to about 200,000 telephone circuits.

A new undersea fiber-optic cable which will connect Europe with the Far East is in the planning stage. This cable will go from Europe through the Mediterranean, the Red Sea, the Indian Ocean and into the Far East. The capacity of this cable could reach the equivalent of more than half a million telephone calls.

The need for repeaters has been a challenge for the manufacturers of trans-oceanic fiber cables. These repeaters need electric power from copper wires, which must be run in addition to the optic fibers in a trans-oceanic fiber-optic cable. The distance that can be covered without repeaters has been increasing due to new fibers, transmitters and receivers. Also, new optic amplifiers may reduce the complexity of new trans-Atlantic cables. Optic amplifiers amplify the optic signal without first converting it into an electric signal. The optic amplifiers also require an electric current supply.

The rapidly evolving fiber-optic technology may offer many interesting capabilities to ham radio. It is therefore well worth the effort to pay attention to this interesting technology and its growing capabilities.

FEEDBACK

In our continuing effort to present the best in amateur radio features and columns, we recognize the need to go directly to the source—you, the reader. Articles and columns are assigned feedback numbers, which appear on each article/column and are also listed here. These numbers correspond to those on the feedback card opposite this page. On the card, please check the box which honestly represents your opinion of each article or column.

Do we really read the feedback cards? You bet! The results are tabulated each month, and the editors take a good, hard look at what you do and don't like. To show our appreciation, we draw one feedback card each month and award the lucky winner a free one-year subscription (or extension) to 73.

To save on postage, why not fill out the Product Report card and the Feedback card and put them in an envelope? Toss in a damning or praising letter to the editor while you're at it. You can also enter your QSL in our QSL of the Month contest. All for the low, low price of 29 cents!

DSP—it seems that you just can't avoid hearing these three letters today anywhere analog signals are in use. Amateur radio gear is no exception. Manufacturers of just about anything that uses filters have jumped on the DSP bandwagon—taking advantage of this up-and-coming technology. The subject of this review—AEA's DSP-2232—is a great example of how DSP can bring intelligence and flexibility to a product traditionally hardwired for a job.

The AEA DSP-2232.

What is DSP?

DSP stands for Digital Signal Processing. DSP uses microprocessor technology to simulate analog filter circuits (in the case of the DSP-2232, the filters used in the modems). DSP has two principle advantages over traditional analog filter design. First is performance: A DSP filter can have very good skirt characteristics. The "skirt" of a filter is the slanted line you see on either side of the filter's frequency response when you plot it on paper. DSP filters are exceptionally sharp, much sharper than even very expensive and sophisticated analog designs.

The second attraction of DSP filters is the fact that they are "virtual." That is, they really only exist in the "mind" of the computer as software. This makes impossible things possible. There are things that a DSP-based filter can do that no amount of time, energy, and money could do to an analog filter. For example, DSP can be used to create "adaptive" filters that actually change their characteristics on-the-fly to adapt to changing conditions. The soft nature of DSP filters also means that new filters—hence new modems, for example—are only a download away. A controller like the DSP-2232 need never become obsolete, thanks to DSP. New mode? Download the firmware and you are on the air. (Note: As of this writing, AEA has not yet set up their BBS to allow downloads, but it is their intention.)

Inside the Unit

The heart of the DSP-2232 is a 24 MHz Motorola 560001 DSP chip. This specialized IC provides the modems for all operating modes. The list of supplied modems is

impressive:

- 300 bauds HF packet (FSK)
- 1200 bauds VHF packet (FSK)
- 2400 bps packet (DPSK)
- 1200 bps packet (BPSK—satellite)
- HF RTTY (FSK)
- Morse
- Facsimile
- SSTV (256 levels)
- 9600 bps (FSK—KK9G)
- 1200/4800 bps ASCII (satellite)
- Dual-port 300/1200 or 1200/1200 packet
- Dual-port RTTY or AMTOR/1200 baud packet

The DSP-2232 uses a Zilog Z-180 embedded microprocessor to handle protocol conversion—that is, to deal with the logic of maintaining an intelligent connection like packet or AMTOR. On the back of the unit are two radio interface ports which operate simultaneously, allowing true dual-port operations in some modes. The DSP-1232 is a single-port version of the controller, though it too provides radio interface connections which may be used one at a time. These radio connections are traditional 5-pin DIN connectors and the manual provides diagrams for connecting the unit to most popular radios using the supplied cables. The five lines available at the interface are: receive audio, transmit audio, PTT capable of +25 to -40 VDC, squelch input, and ground.

Each radio is also supplied with a direct FSK (Frequency Shift Keying) output—available from a single 5-pin DIN—for high speed operation, and a CW keying output (RCA jack)—positive or negative—for Morse code operation. Next to the CW outputs is a satellite up/down frequency control output for Doppler compensation. The current firmware does not use this jack, though some frequen-

cy compensation scheme is in the works.

The computer or terminal device is connected to an AT standard 9-pin D connector which provides RS-232 I/O. The unit is also capable of driving a Centronics parallel printer directly through a 25-pin D connector. Power for the DSP-2232 is a nominal +13 VDC (12-16) @ 1.1 A through a coaxial power connection on the rear panel. No power supply is provided, though a terminated pigtail is included for connection to your shack's supply.

The DSP-2232 is housed in a sturdy aluminum cabinet with an attractively silk-screened front panel. In addition to a full set of standard LED status indicators, the unit sports an easy-to-read backlit LCD display which provides plain text status messages—a very hale feature. Between the LCD and LEDs are two LED bar graph tuning indicators—one for each port.

The Manual

I have mixed feelings about AEA's manuals. As is typical for AEA controllers, the DSP-2232's is quite complete as far as technical information goes. In addition to the extensive radio wiring information, AEA has provided full schematics for the unit. The manual provides step-by-step installation and check-out instructions and extensive tutorials on the various operating modes. Also included is a complete and well-written reference to the commands understood by the controller—though it is not broken down by mode. So, what's the problem?

Most of the beginning users that I spoke to had a hard time getting started using the AEA manual, even with the extensive information provided. It seems that there is no middle ground in reading it. A novice must go through the (potentially) tedious installa-

tion process outlined in the manual step-by-step to use it. Though the described procedure is an excellent one, there is much that could be left out unless a problem arises. Many of the users I spoke with found this process daunting—taking nearly a day to complete in some cases. To be honest, though, I'd much rather use an AEA manual with whatever its flaws than most others I have seen. The AEA manual has the information you need, if you can find it.

Compatibility

The DSP-2232 control firmware is essentially the same as the venerable PK-232. This is good news for those of you who wish to upgrade your PK to a DSP—your current terminal software will work. Those using the PC-Pakratt II (or MacRatt) terminal software will find operation the same. One thing that will need to be improved, though, is the 1-bit (black and white) facsimile display. The DSP-2232 can produce gray scale fax images, but PC-Pakratt II cannot use them. Those of you just starting with AEA products will be able to use any terminal program you wish. If it works with a telephone modem, it will work with the DSP-2232—except for fax.

Performance

If performance is the bottom line, then I

recommend the DSP-2232 without hesitation. On VHF packet, the unit performs like a champ. This isn't too hard, and most TNCs/controllers do. On HF, though, the DSP-2232 shows what it can really do to pull packet, RTTY, and AMTOR signals out of the mud, which other units will not. AEA has lived up to their own tradition of top-

"If performance is the bottom line, then I recommend the DSP-2232 without hesitation."

notch HF performance. Though I was not able to test it myself, those I have spoken to who use the DSP-2232 for satellite operations are very pleased with its performance there—the only disappointment being the lack of Doppler shift compensation at this time.

Some Flaws

The DSP-2232 is not perfect; what is? The good news is that what is lacking is software. All of the complaints are not-yet-implemented features. The frequency

up/down control, for example. There is also currently a lack of software to take advantage of the SSTV and gray scale facsimile, but these are on the way. The DP-2232 is a relatively new product using a relatively new technology. AEA has been very responsive in correcting problems as they are brought to light, and adding features as the production schedule allows. For example, a FACTOR upgrade for the unit is due out soon. This will be a software upgrade—proving the value of DSP.

The other area that some might consider a problem is cost. The DSP-2232 is not cheap. On the other hand, "you get what you pay for" applies to this product as much as any. The box is protected against obsolescence by its DSP technology until our digital modes exceed its computer power. This will certainly happen someday, but it isn't an imminent concern.

Conclusion

If the price isn't a problem, I can recommend the DSP-2232 without hesitation. It is truly state of the art. Those of you involved in high speed packet, satellite, or HF operations will have a hard time doing better at any price. The DSP-2232 has a safe future. As the VHF packet and HF digital networks mature, the DSP-2232 will follow with just a change of firmware.

DSP NOISE FILTER

IMPROVE RECEPTION!

NEW!

- **Reduce noise and interference!**
-Adaptive noise filter for SSB
- **Eliminate heterodynes!**
-Multiple automatic notch filters
- **Sharp CW, RTTY and SSB filters!**
-Linear phase FIR filters
-Highpass, lowpass & bandpass

Digital Satellite Gateway Nodes

How to get on OSCAR 22 with an HT.

by John A. Hansen WAØPTV

Ken KE2SR, who lives near Buffalo, New York, is a fairly new Technician class ham who uses his Commodore 64, a Digicom modem, and an HT to communicate on packet radio with hams in Australia, New Zealand and elsewhere around the world via the orbiting satellite OSCAR 22. Impossible, you say? Not at all—he simply uses his local packet satellite gateway node.

The satellite gateway node system is a fairly new development in packet radio satellites. It permits region-wide access by hams with anything from very modest equipment to the latest in digital satellite technology. You don't need a satellite transceiver, you don't need satellite antennas, and you don't need any specialized modems. All you need is a standard bare-bones packet station that is capable of connecting with your local BBS. The "catch" is that there must be a BBS in your area equipped as a satellite gateway node.

The satellite gateway node software automates the interface between a standard packet radio bulletin board system and a high speed (9600 baud) satellite ground station. All users of the BBS (and all other BBSs in the region) can have access to directories of the files available on OSCAR 22, can mark files to be downloaded the next time the satellite is overhead and have those files imported directly into the BBS, and can upload files to the satellite. In short, they can do virtually everything with the OSCAR 22 satellite that they would be able to do if they spent several kilobucks setting up their own satellite ground stations.

About OSCAR 22

UoSat-OSCAR 22 has been in orbit more than a year now. It was built by the University of Surrey in England and represents the current state of the art in digital satellites. It is essentially an orbiting bulletin board with 8 megabytes of on-board storage. The uplink is on 2 meters and the downlink is on 70 cm. Both the uplink and the downlink are FM and run at 9600 baud. Files can be uploaded and received at a very fast rate.

It is possible, for example, to upload a 100K file in about three minutes. Depending on the level of congestion on the satellite, it is possible to receive files from the satellite at about the same rate. On a typical satellite pass of 13 minutes duration, over half a megabyte of data can be obtained. For the most part this data is compressed, so the amount of actual uncompressed data received is quite a bit greater.

Typically, OSCAR 22 passes over any point in the United States six times per day, with three passes in the morning and three passes in the evening. The passes are about 10 to 15 minutes in duration and are spaced about an hour and a half apart. Because of the high data rates used on OSCAR 22, the variety of material available on this satellite is much greater than on a standard terrestrial BBS. In addition to messages between individual hams, there are photographic images taken by the on-board camera; public domain software packages; schematic diagrams; digitized images of hams, their stations and the areas where they live; and digitized voice files. There has been something of an explosion of dig-

ital experimentation on this bird as people have begun to appreciate the implications of being able to easily transfer files that are measured in hundreds of kilobytes rather than in bytes or kilobytes.

Ground Station Requirements

Ground station requirements are fairly modest, requiring FM radios on 2 meters and 70 cm and vertical antennas with a preamp on the 70 cm side. As a practical matter, however, most ground stations access this satellite with OSCAR-13-class stations (high gain, directional antennas) so that in heavily populated parts of the earth, such as the United States, access with vertical antennas is difficult. There are a few other difficulties as well. The radios used must be capable of 9600 baud transmission/reception and the TNC used must have a 9600 baud modem. Because the satellite moves across the sky, there is a problem tuning the radio during the pass to correct for the Doppler shift. The technology is available for automatically tuning the radio and pointing the antennas, but it is difficult to accomplish this cheaply.

Satellite tracking software will let you know when the satellite is within range.

Notes: Neither ZL2ATI nor KB2OUT own satellite stations, yet they appear on this directory as if they did because they are using gateway nodes.
File a776 is a digitized picture.

Figure 1. Typical Uo22 directory file as it appears on the BBS.

A typical Uo22 ground station consists of a modified Yaesu FT-736R (or ICOM 275/475 or 970 or Kenwood TS-711/811 or 790), a 9600 baud modem, a pair of satellite antennas (such as the KLM 40CX and 22C) and a computer-driven rotator (such as the Yaesu 5400). Many other combinations are possible and it certainly is possible to operate Uo22 with less expensive equipment, but this is a typical station configuration.

Enter the Gateway Node

Many people would like to have the benefits of operating Uo22 but are unable to make the investment required. The Satellite Gateway Node software was designed to meet this need. It integrates a fully-automated satellite ground station with a standard terrestrial BBS. It runs entirely unattended and requires little more sysoping than does a stand-alone BBS. Here is how it works.

Twice a day (after each set of satellite

passes) a directory of the most recent files available on Uo22 is placed on the terrestrial BBS. BBS users can then read that directory (by simply reading the message containing it) to find out what is available. (A typical directory file is displayed in Figure 1.) The directory shows the file number, the file size, who the file is to and from, the date the file was uploaded, the filename, and a subject for the file. In addition, in the "T" column, it shows whether each file is an ASCII type or binary type file. When BBS users request ASCII files, the files are imported into the BBS as standard messages directed to the individuals who requested them. When BBS users request binary files they are moved to a specified subdirectory on the BBS where they can be downloaded by the users who requested them. In the latter case the user is sent a message telling him that his binary file has arrived.

If a BBS user wishes to obtain any of the files in the Uo22 directory, he merely sends

a message to UO22MK @ UO22MK that contains a list of the file numbers he wants. Each time a file is received from the satellite it is placed in a special subdirectory. When someone requests a file from the satellite using the UO22MK procedure, the gateway node first checks this subdirectory to see if the message already exists. If the message exists, it is immediately uploaded to the BBS. If not, it is marked for automatic downloading from Uo22 on the next pass. This is why the system is called a NODE. Files are stored on the gateway node so that a file is never requested from the satellite more than once.

It takes awhile to get used to having to enter a request for a file and then wait until later to actually receive the file. As a practical matter, however, this is what satellite ground station owners have to do as well. Files obviously can only be obtained when the satellite is actually overhead, so users must wait until the satellite comes up, re-

Clock It Quick

Tame ripple counter chips.

by Eddie J. Arnold

This article will teach you how to tame ripple counter chips, such as the CD4020, CD4040, and CD4060.

Back in 1988 a guy asked me to build him a timer circuit that would require his kids to put a certain amount of money into a coin slot, thereby allowing them an allotted period of time to watch television. The idea was novel, I thought.

I got the bulk of the circuit working, but not the timing portion. I was using the CD4060 chip in this particular application. I started playing around with certain guessed values to get a "feel" for what kind of time I could expect to receive at respective pinout locations. I was looking for 60 minutes on one pin and 30 minutes on the other, and I also needed 15 minutes on a pin. I can't tell you how many hours I played with that circuit.

The obvious question came to mind: How could I quickly and consistently use the clock portion of the timing chips? This article will provide you with formulas, an example, and even a program written in GW-BASIC. The information presented is straightforward and simple to implement.

Formulas

The following conventions will be used in this discussion:

F = frequency (hertz)

T = time (sec)

2^n = relates to positional value of a positive pin location.

EXAMPLE:

Chip: CD4060

Time: 60,30,15 minutes

Outputs: Three needed for the above times.

Hint: The highest output available is 2^{14} , and remember that there are no outputs for divisions of 2, 4, 8, and 2048. Design for longest period of time, allowing for pin locations for shorter periods to be detected.

See Figure 1:

Oscillator frequency = $2^N/\text{time(sec)}$

Select pin #3 (2^{14}) = dec (16384)

= 2^N . Use for 60 minute outputs.

Results: $16384/(t \times 60\text{sec}) = 4.66 \text{ Hz}$

= (F) frequency

Pin #3 = 60 min.

Pin #2 = 30 min.

Pin #1 = 15 min.

Remember that for the internal oscillator of the CD4060 the following is true:

$F = 1/(2.2 \times R1 \times C1)$. Note: 2.2 in the formulas is the time constant for the circuits.

$C1 = 1/(2.2 \times R1 \times F)$

$R1 = 1/(2.2 \times C1 \times F)$

To use the CD4020 and CD4040 you must use an external oscillator circuit, such as the 555 timer. Simply build this circuit so that its frequency output matches that of the one shown on the GW-BASIC program.

Using the Program

The program is based on the assumption that you want to produce a certain time output at a particular pin number of CD4060 and some similar chip.

To use chips other than the CD4060 you must list line #1100 and insert appropriate decimal weights for the pinouts of the chip you intend to use. The commas in line 1100 are to prevent pins that are not outputs from getting mixed with the pins that your chip is using. So, if you modify the program you must align this location properly or else your data will be faulty. (See the program listing.)

There are several possible applications for this program:

1. Trigger tone circuits (ham radio).
2. Base of an extended timer circuit.
3. Time-to-binary-weight converter. (Is this a new thought?)
4. Morse code test timer (words per minute).

Conclusion

TYPE load "time" to load the program. Modify the program to your delight. There is ample room for many enhancements. Save time and prevent brain damage using this helpful program. Have fun!

See the program listing on the bottom of page 24.

Digital Satellite Gateway Nodes

Continued from page 20

ardless of whether they are requesting a file from their own ground station or from a gateway node.

To respond to a message that a BBS user has obtained from the satellite the user can use the SR (send reply) command, just as he would to respond to a message that came from any other source. The response will automatically be routed to the satellite. Furthermore, users may initiate satellite contacts by uploading messages either to other satellite users or to ALL, just as they could on a terrestrial BBS. They do this by using the SB (or SP) command: SB ALL @ UO22UP. The destination UO22UP tells the BBS to route the message to the satellite. Messages that come from satellite gateway node users appear on the satellite just as they would if the gateway node user owned and operated his own satellite ground station. In Figure 1, for example, message A70F is from KB2OUT to ZL2ATI. Neither of these stations actually owns their own satellite ground station, yet they appear on the satellite directory just as if they did. Thus, when you see messages on the satellite directory it is impossible to determine whether they came from satellite operators who used their own ground stations or from satellite operators who used a gateway node.

Once a BBS user has uploaded any message to the satellite, his call and home BBS are placed in a special file of satellite users. In the future, any files that appear on the

satellite addressed to this station will be automatically received and imported into the BBS without any action being taken by the BBS users. Thus, the interface between the BBS and the satellite ground station is essentially seamless.

The satellite gateway node is available not only to users of the BBS that is at the gateway node site, but to all other BBSs in the region as well. All the additional BBSs need to do is make sure that all messages that are either @ UO22MK or @ UO22UP are forwarded to the BBS that is at the gateway node site. The gateway node keeps track of the home BBS of each node user and automatically routes all of his or her messages to that BBS. Thus, one gateway node can serve an entire region. In fact, there are significant savings that occur as the service region expands. Since each file is only downloaded once, no matter how many stations request it, as more and more stations use any one gateway node the proportion of file requests that actually involve downloading from the satellite will fall.

How to Establish a Gateway Node

A gateway node consists of a fully-automated satellite ground station (including automatic radio tuning and antenna pointing) and a standard terrestrial BBS. These are fairly stiff requirements (generally in the \$3,000 to \$5,000 category for everything if purchased new), yet there are a

great many such stations currently in existence. Furthermore, since this is no more than the cost of many repeaters, it might be an appropriate project for a club to undertake. Generally, the system will involve a multitasking system such as Desqview, with the BBS running in one window and the gateway node software running in another. Aside from the satellite ground station software (which is available from Compuserve and other sources), all of the software that is needed to run the gateway node is available from the author free of charge. The disk contains complete documentation for setting up the system and a discussion of hardware and software choices that are available. Simply send a formatted disk and a return disk mailer.

It is hoped that the satellite gateway node system will bring the latest in digital satellite technology to many people who would otherwise be unable to participate. It is also hoped that by providing an opportunity for hams to participate in satellite operation without purchasing satellite equipment, congestion on the satellite will ultimately be reduced.

Please remember that amateur satellites are not cheap to build or launch. If you find that you are enjoying using these birds either directly with your own equipment or indirectly using the gateway node system, please support the production and launch of additional satellites by becoming a member of AMSAT.

GW-BASIC program.

Dual Half-Wave Antenna

A ground independent antenna with gain.

by Jack Kuecken KE2QJ

In the early days of broadcasting, Ballentine¹ showed mathematically that the maximum ground-wave field strength would be produced by a 5/8-wave vertical antenna. The 5/8-wave radiator is theoretically 2.9 dB superior to a quarter-wave and 1.2 dB better than a half-wave. Because of the gain advantage, the 5/8-wave vertical is relatively popular in 2 meter mobile applications, despite a few drawbacks.

By 1934, Friis, Feldman and Sharpless² at Bell Labs had shown that a vertical half-wave antenna consistently showed a superiority of about 4 dB compared to a vertical quarter-wave, despite the fact that the theoretical advantage is only 1.7 dB. They reasoned that the losses in the counterpoise were much greater for the quarter-wave since the maximum current occurred at ground level. By comparison, the current maximum is halfway up the radiator on the half-wave and the minimum is at ground level.

Mobile Antenna Background

At the U.S. Army Signal Corps labs, Brueckman³ showed that for mobile antennas, coupling to the vehicle and dependence upon ground can be minimized by placing a current minimum at the antenna base. This decoupling provided much improved circularity in the radiation patterns and made antenna tuning independent of the vehicle type and size. This work led to a number of developments in military "antennas^{4,5}", including the very widely used AS-1729 autotuned antenna, which covers the military 30 to 76 MHz FM range.

For my own 2 meter mobile setup I developed the antenna illustrated in Figure 1. I drive a convertible, which presents several problems. First, you cannot mount the antenna on the roof; second, the car seems to have more electrical noise than a closed sedan. Since the radiating element is a half wavelength high, the current at the base of the antenna is minimal and the coupling to the car skin is minimized. The noise pickup from this antenna is significantly lower than the noise pickup from a quarter-wave type. I have not actually measured the circularity of the radiation patterns on the car but no noticeable nulls exist. Since the 5/8-wave-length antenna does not have a current minimum at the base it does not enjoy the benefits of ground independence.

The small LC network at the base of the antenna provides an efficient transformation

Photo A. The 2 meter mobile antenna mounted on a car. The two hooks catch the edge of the truck lid and the nylon string under tension holds the whole unit on via a hook caught on the lip of the trunk.

from the very high impedance of the radiator (about 2,700 ohms) to the 50-ohm transmission line. The antenna covers the range from 144 to 148 MHz with a maximum VSWR of 1.6 at the band edges and about 1.1 at band center. I found that with a 3" x 5" ground plane the antenna remains matched even sitting on a wooden cabinet! I installed one of these antennas at the peak of my roof for a base station antenna and have been delighted with the results. The lack of a requirement for a counterpoise is a significant advantage.

Two Half Waves in Phase

In the interest of narrowing the elevation pattern and obtaining more gain from the omnidirectional base antenna, I considered using two half-wave vertical antennas, one above the other, phased to add in the far field.

Figure 2 shows that the generator driving

the two from a center gap produces currents which are in phase when viewed from a distance, although they are obviously out-of-phase at the generator terminals. The free-space patterns shown in Figure 3 illustrate the results to be expected. The dual half-wave antenna will provide a pattern which is 52 degrees between elevation half-power

Figure 1. The ground-independent vertical half wave.

Figure 2. Two half waves in phase.

Figure 3. Elevation patterns of half-wave and ground independent dual half-wave.

Figure 4. Antenna circuit.

points, compared to 78 degrees for the half-wave. Furthermore, the directivity will be 1.4 dB higher than the half-wave. Note that the elevation pattern has fourfold symmetry and only a quarter of the pattern is plotted.

The narrower elevation pattern is an advantage by itself. For one thing, it reduces the reflections from passing aircraft (which can cause a considerable flutter in the received signal). Secondly, it reduces the reflections from foreground objects, which can distort the pattern.

The Antenna Construction

After several false starts I developed the feed circuit shown in Figure 4. I had some lengths of 7/8" o.d. aluminum tubing from a scrapped array. These were used for the radiators. Experimentally, I found that the highest impedance resonance at 146 MHz, for this tubing diameter, could be obtained with 38" radiators. By jiggering the values of C1, C2 and L1 it was possible to obtain a very good match to 50 ohms. A measurement of current magnitude and phase showed that the radiator currents were equal and in phase as seen in the far field.

Figure 4 is intended mainly to clarify the matching scheme. The construction is shown more clearly in Figure 5. The coax feed cable was actually run up the center of the lower radiator. The dielectric beads at the upper and lower radiator ends are used to center the coax and to provide a measure of tuning. At the center of the lower radiator a shorting

Figure 5. Basic construction.

plug is inserted which shorts the outer conductor of the coax to the inside of the lower radiator, thereby making AB and DC a pair of quarter-wave (not quite) coaxial chokes. The coax used is 0.140" o.d. semirigid 50-ohm cable. If the shorting plug is made of brass it may be soldered directly to the copper tubing outer jacket of the coax. If the plug is made of aluminum, fashion a brass or copper sleeve which can be soldered to the coax and connected to the aluminum with screw pressure. One source for the miniature semirigid coax is Precision Tube Co. Inc., Microwave Division, Church Road and Wisnicksen Ave., North Wales PA 19454.

The two little capacitors used are Johanson air variable 0.7-to-10.5 pF units. I picked these up at a hamfest for a few cents. A pair of piston caps might be better since they can handle more power and are easier to tune. The inductor consists of three turns of #16 tinned wire wound on a 3/4" form. We will discuss tune-up later.

The insulators for this unit were made from white PVC water pipe. The construction is shown in Figure 6. The construction technique used on this model is best suited to those who have a lathe available, but other constructions not requiring a lathe are also feasible.

The radiators are, as noted earlier, 7/8" o.d. aluminum tubing. In order to get a good fit, the nominal 1" pipe, which is actually 1.063" i.d., must be shimmed. To do this I cut two 1.25" lengths of the pipe. I then cut out a portion of the circumference so that I could compress the remaining segment into a 1" diameter cylinder. I then slathered some PVC pipe glue on the center piece and the insert and drove the insert in with a soft mallet. Immediately upon insertion, clamp the insulator in a vise to round up the egg shape that develops because of the uneven push of the insert.

The PVC glue dries very fast. When the first end of the center insulator is done, do the other end. After the glue has dried for about a half hour the insulators may be bored out in a lathe to give a good fit for the upper and lower radiators. After the boring operation, the center insulator should have a center window about 1/2" x 1" opened to permit connection to the coax.

The base insulator is made similar to the center insulator except that only one end is equipped with an insert. The base flange is made of any convenient material. It may be either metal or plastic. It must, of course, be strong enough to hold the overturning mo-

ment due to wind loads on the radiators. In my case, I made it by laminating two pieces of 3/8" XXXP plastic (a paper-base melamine) and boring the assembly to accept the base insulator outside diameter.

Assembly

To begin with, prepare the ends of the miniature semirigid coax. At each end mark

All amplifiers (non-rpt) are linear, all-mode with fully automatic T/R switching and PTT capability. The receive preamps use GaAs FET devices rated at 5 dB NF with +18 dBm 3rd order IP. LPA, Standard and HPA amps are intermittent duty design suitable for base and mobile operation. Repeater amps are continuous duty, class C.

Amplifier capabilities: High-power, narrow or wideband; 100-200 MHz, 225-400 MHz, 1-2 GHz, Military (28V), Commercial, etc. - consult factory. A complete line of Rx preamps also available.

CIRCLE 232 ON READER SERVICE CARD

off 1/4" from the end and carefully score a circumferential ring in the outer conductor tube with a sharp knife. Grasp the piece with a pair of pliers and gently work back and forth. The outer tube will break circumferentially along the scored ring and the piece can be pulled off. Next, cut the Teflon™ insulation at a point 1/8" from the end of the tube, as shown in Figure 8. Take care at this point not to score the center conductor.

If the shorting plug is brass, slide it into position on the coax and solder it into place. If the plug is aluminum, slide the protective brass bushing into place and solder it. The shorting plug should be placed so that the prepared end of the coax projects beyond the end of the lower radiator into the center of the gap between the upper and the lower radiator.

The dielectric beads can be made from polystyrene, G-10 epoxy Fiberglass™, Kel-F, Teflon or other dielectric with a low dissipation factor at 146 MHz. Do not use plexiglass or melamines. These washers are easily turned on a lathe but may be filed out by hand. A perfect fit is not necessary; however, the coax should not rattle too much.

Next, slide the dielectric beads onto the coax. These may be held in place with a drop of epoxy. The beads should be positioned to fall in the open ends of the lower radiator and should hold the coax centered.

The next step is to install the BNC connector. There are cable connectors made to directly accept the semirigid coax but they are not often seen at hamfests. Figure 8 shows how a standard BNC connector can be adapted to this coax. I used a UG-291B/U female so that a normal, male-ended cable can be attached without an adapter. The adapter brushing is used to make the coax fit the connector. First slide the nut, the flat washer and the gasket on the coax. The washer may have to be reamed slightly to fit over the shank of the adapter. The bushing is then slid onto the end of the coax with the flange flush, with the end of the outer conductor and sweat soldered in place. The pin is then soldered to the center conductor and the connector assembled. The piece which normally holds the braid and interfaces to the gasket is not used.

Leads of approximately 1.5" are next soldered to the end of the coax which will go into the insulator. Bend these leads more or less parallel to the axis.

If an aluminum plug is used, drill and tap a radial hole from the periphery of the plug to the hole for the bushing. Insert a 4-40 headless setscrew to lock the bushing in place.

Next, mark and

drill a #39 hole 19" up from the base of the lower radiator. Mark the center of the shorting plug and slide the coax into the lower radiator until the mark shows through the hole. Drill and tap for three 4-40 flathead screws to secure the plug. Flathead screws permit one to slide the lower weather seal up the lower radiator.

Next, fasten the center insulator to the upper radiator. This can be a permanent joint. I use a cement used to mend vinyl and leather, found in shoe and leather stores under the names "Shoe and Leather Patch" or "Shoe Goo." An RTV cement can also be used. Slide the radiator 1.25" into the insulator.

Next, slide the insulator onto the upper end of the lower radiator without glue (you may wish to disassemble this joint later). Now drill and tap through the insulator into the upper radiator and lower radiator to make an electrical connection to each. Sheet metal screws may also be used.

Put a terminal lug on the upper and the lower radiators. Additional screws may be

Figure 6. Center insulator.

Figure 7. Base assembly.

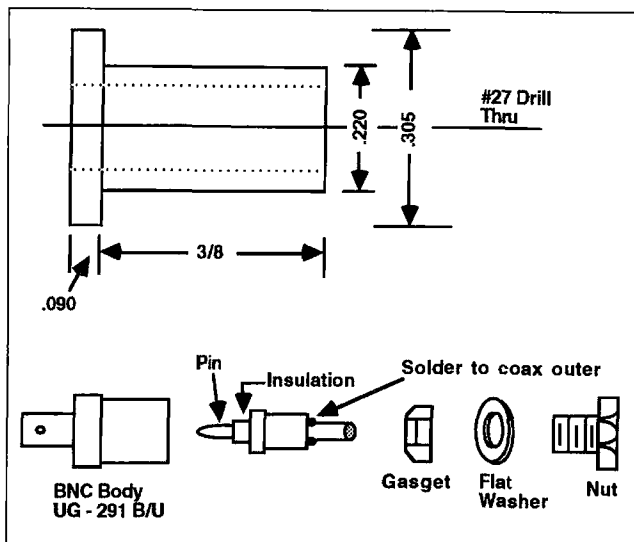

Figure 8. Cable assembly.

added at this point to secure the insulator to the radiators.

Reaching in through the window in the center insulator, pull the leads from the inner and outer conductor out through the window. Solder the coil between the terminal lugs and solder each capacitor between one of the leads from the coax and one of the end terminals on the coil.

Insert the bottom end of the lower radiator into the base insulator and insert the base insulator into the base flange. Mount the antenna somewhere in the open and get ready to tune it.

Tuning Up

For the tune-up procedure you will need a signal source and some form of system to detect the matched condition. A directional coupler or SWR meter can be used; however, I prefer the use of a bridge circuit because it's more accurate. See the *Radio Amateurs Handbook*. In the 1990 edition, Chapter 25, pages 9 and 10 and Figure 21 give suggested circuits.

Set the signal source to 146 MHz. Next, tune the two capacitors for the deepest null available. Try to keep the capacitances equal. The coil was initially close wound; stretch it axially a little bit. This decreases the inductance. Re-null the capacitors, again trying to keep them equal. If the null improves, you went in the right direction. Stretch the coil again and repeat the nulling. Eventually you should reach a point where the inductance is too small and the reflection starts to rise again. Back in to obtain the deepest null possible.

If a reasonably sensitive bridge is used, you will find that as a good null is approached the motion of your body within four or five feet of the antenna will cause the reading to change. It will be necessary for you to de-tune the antenna in such a direction that the match improves as you walk away. Done properly, you should be able to attain a VSWR less than 1.1 : 1 at the center of

the band, running out to less than 1.7 at 144 and 148 MHz. The Smith chart shown in Figure 9 shows the results of a measurement obtained using a General Radio model 1602B UHF admittance meter. The data has been rotated to the center of the antenna at the feed-point. The VSWR's represented range is from 1.63 at 144 MHz to 1.45 at 148 MHz. The tuning can easily be shifted to favor one end of the band or the other.

For weather protection, I cut off a plastic bottle and cut a hole through the bottom of the bottle to closely fit around the upper radiator. This is placed upside down over the coil-capacitor assembly. A bead of RTV or shoe cement is used to seal the upper radiator. On the bottom side, the bottle top was similarly fitted around the lower radiator with the flange down. The lower edge of the upper part hangs below the upper edge of the bottom part. These are not tightly fitted or sealed. Instead, they are designed to be drip-proof and so that some air can circulate. My experience has taught that if you cannot get a true hermetic seal, you are better off to arrange matters so that air can circulate and water and condensation can run out.

The open end of the upper tube can be neatly sealed with a wine bottle cork. The brand is not important. My personal taste runs to dry white wines, however, a cork from a sherry bottle would do as well.

For mounting the antenna, a 3" x 5" or 5" x 7" ground plane is adequate. The BNC fitting should be in the center of the base insulator so that the driving cable is protected from rain, etc. No goopy sealing of the cable should be required. If you wish you can insert a rolled sheet of plastic into the bottom of the base insulator to protect the joint.

Active Antenna Using a MOSFET

Build a low noise antenna.

by Ken Cornell W2IMB

I first became involved with active antennas back in the late '70s while experimenting with communications on the 160 to 190 kHz FCC Part 15 band. Due to the high ambient noise level encountered in this frequency range, the search for an efficient and low noise receiving antenna was an interesting experimental endeavor. The longwires and 50-foot vertical used for transmitting were noise collectors in most locations.

Quite a few of us LOWFERS (short for "low frequency experimental radio station") started to use various designs of active antennas that consisted of a short whip vertical some three to six feet long with a preamplifier built into the base. The antenna was connected via a random length of coax to a receiver coupler located at the station's operating position. Since it is relatively small and lightweight, it was easy to move it around the homestead and place it in the position offering the best signal-to-noise ratio.

The use of JFETs, such as the MPF102, was popular, and I have offered several designs in some printed articles and in my *Low & Medium Frequency Radio Scrapbook* series.

Using MOSFETs

While experimenting with transmitters on the 510 to 1705 kHz band (again an FCC Part 15 band; 100 mW to a 3 meter antenna,) I found that the Amperex BS170 and the ZETEX BS170P were excellent final amplifiers. They are MOSFETs.

I decided to try them out as an active antenna preamplifier. After quite a few breadboard layouts, I ended up with the circuits shown in Figures 1 and 2. I was quite pleased with its performance.

Since the active antenna consists of a short vertical with a broadband preamplifier, I decided to put the entire unit within a five-foot length of white PVC pipe. Placing a PVC pipe cap on each end would make the unit weathertight. A coax fitting is placed in the bottom cap.

The circuit for the active antenna is shown in Figure 1. Since the coax cable provides two functions—one to feed the antenna to the receiver and the other to supply power to the MOSFET—we need a receiver

coupler and a power supply isolator. This circuit is shown in Figure 2.

An SPDT switch is added to the receiver coupler circuit to allow selection of either the active antenna or a reference antenna for comparison purposes, or to select the best antenna for signal-to-noise ratio.

The active antenna circuit is wired up on a 1" width of perf board. I used RG-59U coax cable and installed an F-81 coupler (Radio Shack #278-213), with the long-threaded

shank to the inside, in the bottom pipe cap. The antenna assembly is shown in Figure 3.

The actual antenna is a length of 1" aluminum tubing with a hole for a 6-32 machine screw at each end. The top hole is for securing the aluminum antenna tube to the PVC pipe. The bottom hole is for connecting a short length of flexible wire from the tube to the antenna input on the circuit board. A short length of RG-59U coax connected to a CF-59U male "F" connector is used to con-

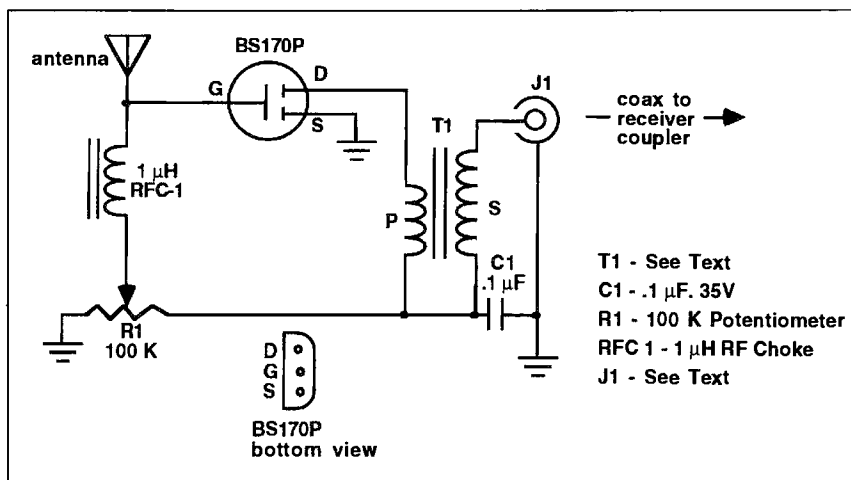

Figure 1. Active antenna.

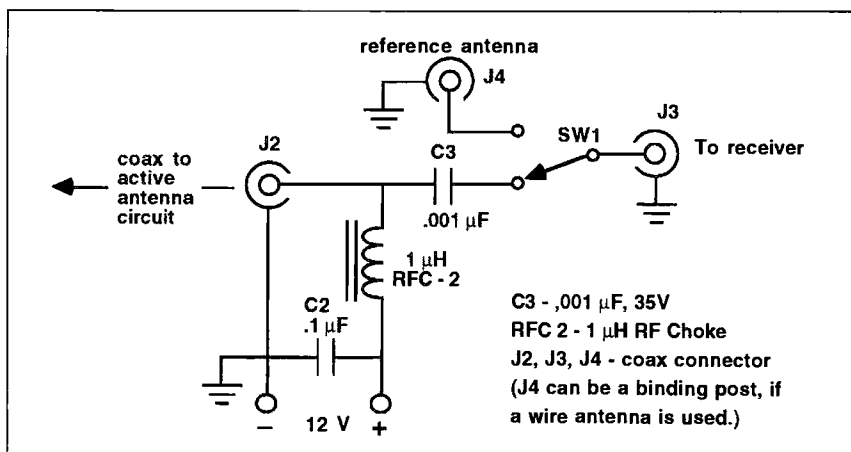

Figure 2. Receiver coupler.

Figure 3. Active antenna assembly.

nect the coax cable feed to the circuit board, as shown in Figure 3.

For testing, connect the coax fitting (secured in the bottom pipe cap) and the antenna to the circuit board, laid out as it would be in the assembly, then connect the active antenna to the receiver coupler and the coupler to the receiver. Apply power. Adjust the 100k potentiometer to provide between 15 and 25 mA to the preamplifier. Then check the antenna for performance. If desired, the potentiometer can be removed and the resistance each side of the arm measured. Fixed resistors could be substituted.

Assembly

The assembly can now be slid into the PVC pipe, starting with the aluminum tube end. The top of the aluminum tube is centered on a predrilled hole in the top of the PVC pipe and the tube is then secured with the machine screw and nut. The bottom pipe cap is firmly pressed on and then drilled and tapped on two sides for 6-32 securing

screws. I suggest using stainless steel fasteners.

The antenna is mounted vertically. I used Radio Shack #15-883 4" wall mounts. The "U" bolts that come with the mounts are not wide enough for the PVC pipe so they are not used. The hole spacing of the outer clamp needs to be made wider. I did this by placing the part on a sturdy support with the "V" shape up, then hitting it with a hammer to spread the holes. I then used 2-1/2"-long bolts to clamp the antenna.

The active antenna output transformer "T1" is wound on an Amidon FT50-43 toroid form. The primary has nine turns and the secondary 18 turns. You can use #26 to #30 enameled wire.

I obtained my MOSFETs from Digi-Key Corp., P.O. Box 677, Thief River Falls MN 56701. I used the ZETEX BS170P. I noted that they also list a Philips BS170PH. ZETEX also offers a VN10LP that experimenters may be interested in.

While the turns and ratio of turns on "T1"

is what I used, some experimenters may try different windings, depending on their favorite range of frequencies. However, it is a

broadband device.

After assembly, caulk the pipe caps and the heads of all screws to insure weather-proofing. I also suggest caulking the coax connector in the bottom pipe cap.

Another scheme for mounting would be to add an eyebolt in the top pipe cap and hang the antenna from a supporting structure. In this case, securing screws should be added to the top pipe cap as in the bottom pipe cap.

Don't just pick a spot to locate the antenna. Use a buddy and move the antenna around to find the quietest location as to the signal-to-noise ratio. Sometimes moving it only a few feet one way or another will make a big difference in the noise level. Also, don't think that adding a long antenna will improve the performance; you will be getting more noise pick-up. The preamplifier will make up for the lack of aperture.

To eliminate the chance of corrosion around the antenna's coax connectors I recommend that, once you have established their location and determined the coax length, you feed the coax directly through the bottom pipe cap and solder it to the circuit board input terminals. Use a cable clamp on the inside and then caulk the cable entry.

Figure 4. PC board pattern and parts placement for active antenna and receiver coupler.

J2 to J4	Your favorite coax connector. J4 can be a binding post if a wire antenna is used for reference.

*1 mH RF choke is for 160 meters and above. For low frequency work (160-190 kHz) try substituting a larger choke, such as 4.7 mH. Circuit boards are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118 for \$4.50 (set of two boards) plus \$1.50 shipping and handling.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

A new high-altitude amateur satellite is expected to be launched and commissioned this April. The French ARSENE satellite is a Phase-3 class satellite with a high orbit and a large complex spaceframe.

The French Connection

Over 15 years ago, a group of amateurs in CNES (National Center for the Study of Space—France) proposed that France should support amateur radio space activity with a major satellite construction project. The idea was submitted to directors at CNES in 1978, where it received favorable response. No financial commitment was required, but the CNES promised support in the form of space-ready parts that were not suitable for future commercial or government projects. The CNES also offered to provide space on an Ariane flight where the entire capacity of the booster was not needed by the paying customer.

The ARSENE satellite program was organized with cooperation from three groups and various individuals. Industry was represented by the CNES, the radio amateurs through RACE (Radio Club de l'Espace) and schools through ENSAE (l'Aeronautique et de l'Espace). The French equivalent of the American Radio Relay League, the REF (Reseau des Emetteurs Francais), joined with RACE to support the program.

By 1979, initial contacts had been made between the three groups involved in the program. They considered proposals for various satellite configurations and final orbits. Complete documentation was expected by the end of 1982 or 1983, with an estimated time for satellite construction of two years. They anticipated launching sometime in 1985. These goals were not met, but instead of dying, the program progressed methodically through the 1980s. Today ARSENE is a reality and is waiting for launch on an Ariane type 42L launcher with the geostationary TV satellite ASTRA 1C from French Guiana.

ARSENE Today—The Satellite

At launch, ARSENE weighs 150.6

kg. It has six sides, not including the top and bottom. The main unit's diameter is 785 mm, the height is 618 mm. Encompassing the maximum extension for antennas and other portions of the satellite, the dimensions increase to almost a meter in diameter and over a meter in height. The satellite will be spin-stabilized around the north/south axis, which will be held perpendicular with the equatorial plane of the earth. Attitude control will be handled by nitrogen jets.

Power for the spacecraft comes from GaAs (Gallium Arsenide) solar panels from Italy generating 60 watts. The communications payload supports a digital Mode B (70 cm up and 2 meters down) and an analog Mode S (70 cm up and 13 cm down). Note Table 1 for a list of operating frequencies by mode. The two modes cannot be operated simultaneously, but will be controlled by a schedule to be determined after launch.

The digital Mode B system represents a departure from the current use of PSK or high-speed FSK in use on most current microsats and Uosats. ARSENE employs standard AFSK (Audio-Frequency Shift Keying) AX.25 packet. With three uplink frequencies on 70 cm and a single downlink on 2 meters, the system can be accessed by anyone using a standard TNC (Terminal Node Controller) in conjunction with appropriate VHF and UHF radios and antennas. No special modems or radio modifications are required.

The 2 meter downlink runs 15 watts out in the high-power mode and 2 watts in low-power. Packet operation is specified at 1200 bps with standard 1200/2400 Hz tones. The system works as a digipeater and does not support an on-board mailbox. The possibilities for such a satellite system are endless, but congestion is expected to be a problem.

The Mode S transponder is 16 kHz wide but will support any type of modulation that is sent on the 70 cm uplink and fits the channel. Power output is 800 mW. The downlink frequency is quite distant from that used for AMSAT-OSCAR-13 (over 40 MHz), so modifications to current Mode S receivers will be necessary.

The Orbit

The desired orbit for ARSENE is equatorial with an apogee (high point of the orbit) of 36,000 km and a perigee (low point of the orbit) of 20,000 km. The Ariane rocket will place the satellites in a geostationary transfer orbit. This transfer orbit is highly elliptical and, due to a low perigee, is not suitable for a final orbit. The ASTRA satellite will then be boosted to a geostationary position over the equator. ARSENE has its own solid-rocket motor. At the apogee of the fourth orbit the main ground control station will command the firing of the internal booster. This will give ARSENE its final orbital characteristics with a period of 17.5 hours. The ground track should closely follow the equator. Good access is expected

even for stations above (or below for the Southern Hemisphere) 60 degrees latitude.

Operating with ARSENE

Activity via the Mode S analog transponder will at first be quite light due to the downlink frequency in use. The satellite's operating schedule will likely allocate only a small portion of each day to Mode S. Terrestrial 13 cm systems use 2304 MHz and A-O-13 operates near 2400 MHz. ARSENE's use of 2446 MHz will likely be responsible for conversion and new construction articles. Link margins show that uplink requirements will be similar to A-O-13, i.e. about 300 watts ERP (Effective Radiated Power). This can be accomplished

Restoring the Classics

It only takes one hamfest to learn an elementary truth: Such events are games of musical junk. That is, people trade favorite or despised rigs and equipment of earlier times for other people's favorite or despised rigs of other times. And, in some cases, spouses cast a wary eye on all that wonderful stuff coming in the back door after every hamfest.

Well, why not put some of that equipment back on the air? I mean it—after all, we don't all need to use a multikilobuck Super Bandbuster IV SSB transceiver with its Flaming Blowtorch 2000 linear amplifier. Besides the ham who simply cannot afford such things (as I was when I was a kid), there are also hams who can afford the Blowtorch and Bandbuster, but who like to work on supposedly antique radios.

Because my electronics experience spans both the vacuum tube era and the solid-state era (which is continuing, of course), I find myself at home with a variety of equipment. If you are not, and want to learn some basic tube theory, then look at any of the earlier editions of *The Radio Amateur's Handbook* or, if you will permit a commercial plug, see

my antique radio book from TAB Books in Blue Ridge Summit, Pennsylvania (phone: 1-800-233-1128).

Two pieces from my own collection of radio paraphernalia include the Heathkit DX-60B transmitter and the Hallicrafters SX-100 shown in Photo A. These two pieces of equipment would have made a real dandy Novice and General class station in the late 1950s or early 1960s.

What to Look For

There are several generic things that need to be done on nearly all vacuum era refurb jobs. First, if possible test all of the tubes. This might not be possible, even though at one time nearly every drug store and fast-food joint had a tube tester. Today, only older TV shops and antique radio repairers have them. If this isn't possible, then check the radio for

operation and troubleshoot to find weak stages and so forth. My antique radio book gives info on how this job is done.

Next, inspect the chassis, looking for signs of trouble. Look in the vicinity of the power transformers for signs of tar or pitch oozing out. This does not automatically mean that the transformer is bad, but it does tell you that it has been overheated at some point in its career. Note the condition and attempt later to find out whether or not the transformer is good.

Also examine the electrolytic capacitors in the rig (see Photo B). These components tend to dry out over time, and may have to be "reconditioned" or replaced. Reconditioning is done by letting the set work for a couple of hours a day for about a week. On radio receivers that have been stored for many years you may find a high hum level in the output. This symptom indicates that the electrolytic capacitors used in the DC power supply ripple filter are bad. Some of them will reform after being used for a dozen

or so hours. I once "reconditioned" a Hammarlund HQ-145 by letting it run for a week or so. The hum level dropped every day, and finally disappeared before the week was up.

The signs to look for on the electrolytic, indicating replacement, are discoloration of the paper (if tubular), bulging (all types), or any oozing of material at the end caps (all types). In most cases, the oozing will be long over and only a gray, white or tan corrosion or dust remains. If you see this material, replace the electrolytic capacitor. Don't even try to refurbish it.

The general rule of thumb for replacing an electrolytic, especially one in the DC power supply, is that you can use one with the same or higher capacitance rating, or the same or higher Working Voltage DC (i.e. WVDC) rating. If the capacitor appears to be bulged, then suspect that a higher WVDC rating is needed for the replacement. Measure the normal voltage across the capacitor and

then multiply it by 1.20 (this allows a 20 percent margin for error and variation). Next, multiply the WVDC rating of the existing capacitor by 0.80 (also allowing for a 20 percent margin). If the voltage times 1.2 is near (or higher than) the WVDC rating of the capacitor, then opt for the next higher value.

I've seen this problem several times where 350 WVDC capacitors were used in a receiver that should have used 450 WVDC. I recall a medical oscilloscope used for bedside monitoring in hospitals a couple of decades ago. It had a 270-volt DC power supply that used 60 μ F/350 WVDC capacitors in the two sides. They were typically found bulged out after a year or so in service. Note that $1.2 \times 270 = 324$ volts, and that $0.80 \times 350 \text{ WVDC} = 280$ volts. Get the point: Under the worst case, which apparently occurred from time to time, we have a 280-volt capacitor in a 324-volt circuit! With 20 or so of those 'scopes in our system, we were replacing electrolytics on a fairly regular basis. While this scenario is a bit extreme, it does happen. We replaced the capacitors with 60 μ F/450 WVDC units and never had another failure.

Some receivers use a multisection electrolytic capacitor. These capacitors sit upright on the chassis, and may have either two, three or four electrolytic capacitors in a single metal can (although it might have a paper insulating cover over it). All sections share a single common ground connection, which is the case of

Photo B. Power supply electrolytic filter capacitors are often bad after storage, even when they were good when the rig was first placed in storage.

the can. Some old-timers would replace an open-circuited section (a fairly common failure mechanism) by shunting a tubular electrolytic across the bad section. This saves the replacement job, and is cheaper than buying the entire multisection electrolytic capacitor. Like many such "solutions," however, it is simple, elegant, easy and utterly stupid. In other words, it's wrong. Why? Because those electrolytics tend to fail later by shorting out. I've seen that happen so many times that I tend to get curmudgeonly and short-tempered when I see it. Besides, in those years when I worked on medical instruments I saw one case where such a repair might have cost a patient's life. A contractor (not one of us in the hospital lab, thank God) had pulled that trick on a defibrillator, and then the main capacitor shorted. When the patient went into ventricular fibrillation, the docs tried to use the instrument, and it failed. Fortunately, there was one nearby on another unit

Photo C. Capacitor bearing and rotor ground are often sites of problems in older receivers.

and it was brought to the scene post haste . . . but time was wasted. We'll never know whether proper repair procedures would've saved that life, but I know I'll never be party to such a shabby repair. Such are the lessons of life.

Another thing to check is the condition of the switches and potentiometers in the set. Use switch contact or TV tuner cleaner to spray down each switch, especially rotary types, and each potentiometer. Get the stuff inside the component, and then mechanically operate the switch/pot vigorously eight to 10 times to thoroughly clean the insides. I've found antique bandswitches so corroded that only gentle rubbing with a pencil eraser did the trick. Be careful, especially on bandswitches, to not disturb surrounding circuitry.

On receivers of old you will find a massive main tuning capacitor, a multi-sectioned marvel of an air dielectric variable. Wonderful sight, those were! How-

ever, they are also a pain in the neck after 10 or 20 years of unuse. The front and rear bearings supporting the rotor plates are lubricated. The lubricant dries out with time. In addition, there is a ground spring that connects the rotor plates to the capacitor frame. These (usually brass) springs are the electrical connection. If the receiver intermittently howls and screams when tuned, or is excessively microphonic (howls or screams when touched or vibrated), then suspect either the lubricant or the spring.

The lubricant can be cleaned out with spray cleaner, but be sure not to spray the plates. Be gentle with the spritzer button! Replace the lubricant with white petroleum grease such as LubriPlate, or something similar. Some people claim that silicone grease works as well, but I haven't used it so I can't corroborate the claim. Use a toothpick to apply the grease, and then run the capacitor through its entire range several times.

The ground spring needs to be cleaned, especially under the tip that rests on the capacitor mounting plate. Gently raise it—but not too far—and burnish the metal underneath it and on its bottom side. This trick should reground the capacitor and make the radio work again.

Of course, there may be other problems, and they will require normal troubleshooting procedures to find. Those mentioned above are often due to old age or the abuse of nonuse. 73

Q : What Keeps You Twistin' when the lights go out?

A : The EMOTO 201SAX and 201AAX Rotators!

201SAX

201AAX

Professional grade, high performance rotators with one major difference: They both run on 12 volts DC!

The 201 series rotators offer all the features and ruggedness you've come to expect from EMOTO:

- Attractive, easy-to-read 360° circle controller on the standard 201 SAX home station version
- Specially designed compact controller, perfect for outdoor field day, DX-pedition and VHF/UHF mountaintopping on the 201AAX portable version.
- Both models feature a conservative 8 square foot rating and handle most popular 3 element tri-band beams, even full-sized VHF/UHF antenna farms.

This unique product is the logical solution for all ARES/RACES, Skywarn and other emergency stations looking for the ultimate in disaster communications preparedness!

With the EMOTO 201 series rotators, you'll never have to be without your beams 'cause the lights went out!

Fast Packet Ticket!

PackeTwin™ Wireless Communications System (shown)

Thinking about the move to packet? At Gracilis, we've got your ticket—Today and tomorrow.

Using our dual-channel PackeTwin module and your existing IBM® PC or compatible, you can communicate with other packet radio stations throughout the world. Send mail, download files, browse data bases, or just talk to your friends.

When you order our PackeTwin Wireless Communications System, you'll get a plug-'n'-play 9600 baud system, complete with modem and palm-size two watt UHF transceiver. You supply the PC and antenna—*We supply the rest!* If operation at 1200 or 2400 baud is desired, plug-in modems can be ordered for direct connection to your existing transceiver or use with our UHF transceiver.

Consider these important features...

- Dual-channel operation to 19.2kbps—with a single channel capable of speeds to 1Mbps using RS-422 connection and the PC's DMA channels
- Free software that provides access to existing AX.25 and newer TCP/IP networks includes features such as BBS operation, Mailbox, SYSOP chat, and file transfer
- Free product software and firmware updates

For information contact your distributor, or...

CIRCLE 291 ON READER SERVICE CARD

with 30 watts on 70 cm to a 10 dB gain antenna. For the downlink, a GaAsFET preamp and a 2.5-foot dish with coffee-can feed should work.

Mode B will be the most common ARSENE activity. The link margin on the uplink will be the same as Mode S, but due to congestion, it may seem to take much more power at times when the satellite is visible to many users. The high-power 15 watt downlink on 2 meters will be an easy copy on a moderate beam at a home sta-

tion. While signals may be audible on portable equipment with omnidirectional antennas, the packet copy will likely be poor. Since the orbit is quite high even at perigee, there will be no times when the signals will be overwhelming. They will, however, be consistent and show very little Doppler shift.

The French telecom authorities have assigned ARSENE the call sign FX0ARS. Satellite builders have decided to label the AX.25 frames with

ARSENE-1, ARSENE-2 and ARSENE-3, depending on which TNC is transmitting. After launch ARSENE will retain its prelaunch name, although there will be no problem with other international groups that may decide to assign an OSCAR number. Depending on the launch status of other hamsats currently waiting for launch, ARSENE may become known as ARSENE-OSCAR-24 or ARSENE-OSCAR-25.

ARSENE Telemetry

The single 2 meter downlink frequency will carry telemetry information as well as the digipeated packet activity. The data downlink carries information on 30 analog channels and nine satellite status bytes. The format will be unconnected AX.25 frames. Table 2 shows information on the analog telemetry equations as received from Bernard Pidoux F6BVP via Joe Kasser G3ZCZ/W3. Note that the parameter value is denoted by "y" and the variable "v" is the value sent from the satellite to be used in the appropriate equation. The "Units" column shows the type of measurement for the channel where "V" is voltage in Volts, "I" is current in amps, "T" is temperature in degrees Celsius, "P" is pressure in Bars and "W" is power in watts.

The nine digital-format status

bytes include two eight-bit bytes STA and STB that describe the status of 16 on-board systems. Table 3 shows the breakdown of this information. The other seven status bytes include four for message handling and three that represent counter information.

A shareware program (PC) written by FC1OAT to decode telemetry on-line is available from ATEPRA (Association Technique pour l'Experimentation du Packet Radio Amateur), 23 rue de Provins, F-77520 MONS EN MONTOIS, France, Europe. It is compatible with CGA, EGA or VGA displays and requires only the addition of a receiver tuned to 145.975 MHz FM, a standard TNC and an antenna.

Get Ready

ARSENE promises to be an exciting satellite. Its curious orbit and standard packet system set it apart from any other hamsat available for use by all hams. Congestion is expected after this satellite is "discovered" by the ham community. Expect announcements concerning the use of the three uplinks to segregate individual operators, bulletin-board systems and packet clusters. Also expect more emphasis on Mode S operation to get on this satellite and get ready for Phase 3 D later this decade.

I had hoped to present the first part of my solar charge controller this month but, because of several circuit changes, the PC board has to be re-worked and there will be a delay. This is a rather complex circuit so I'll show the charge controller in stages as we go.

The first part of the project will deal with the power supply and the voltage reference, as well as the state of the charge circuits. I'll show you the basic design for the voltage divider used for the battery sense line as well as the array detect circuits.

Power to operate the controller comes from the battery being charged. A 1N4001 diode provides reverse polarity protection for the ICs. The input to the first voltage regulator is decoupled with several low value capacitors. This keeps the IC regulator stable since the supply voltage (the battery) is located some distance from the regulator itself.

A 7812 IC regulator provides a stable +12 volts for the controller. The normal battery voltage will be around 12.6 volts so there will not be enough overhead to allow this regulator to work properly. When the battery voltage is 12.6 volts, the output of the regulator will be about 10.5 volts. When the input to the regulator is approximately 1.5 volts over the minimum needed, the regulator will work properly. When the battery is nearing full charge (14.4 volts), the regulator will have enough overhead and will output its required 12 volts.

If you have a problem with this system you may swap out the 7812 for a 7810 regulator. This is a 10-volt regulator and will work fine on a 12.6-volt

Low Power Operation

battery. They are much harder to find than the 7812, though. However, all the major electronic suppliers do stock the 7810. Radio Shack does not handle this part, but it does carry the 7812.

The output of the regulator supplies VCC to all the ICs. The output also supplies the LM317L regulator. This regulator is a small TO-92 case version of the popular LM317 TO-220 case regulator. A 10-turn 1k trimmer sets the voltage at 4.5 volts. Op amp U2 is configured as a buffer. This buffer provides isolation between the logic and the 4.5-volt reference source. The output is on pin #7. This then becomes our 4.5-volt reference line. The reference line connects to several points on the PC board. If you're building this circuit on perf board, don't forget to connect all these reference lines together.

To generate our state of charge reference voltage, another op amp is used, but this time as a voltage amplifier. The 22.6k 1 percent resistor sets the gain of the amplifier in conjunction with the 0.01 capacitor. The state of charge is then set by adjusting the 470k pot. By increasing the amount of resistance in the circuit you increase the output voltage from the op amp. This then becomes our SOC reference source.

Array detect works by sampling the voltage generated from the array. A voltage comparator made up of an op amp compares the output of the array to the voltage on the battery. If the array voltage is lower than the battery voltage, then the comparator's output stays high. When the array voltage is greater than the battery voltage, meaning the array will be able to charge the battery, two things happen: First, the array ready LED is illuminated; second, the charging LED is also illuminated,

indicating battery charging has begun.

Since this controller uses power MOSFETs, even when they are "off" their internal clamping diode will allow the battery to discharge at night. A Schottky barrier diode in series with the MOSFETs and the battery prevents discharge at night. It also isolates the battery from the array, allowing the array detect comparator to see only the array and not the battery voltage at the same time.

The Schottky diode is an MBR1635. This TO-220 case diode will allow current to 15 amps if the device is properly heat-sinked. You will have to de-rate the device if you don't heat-sink it properly.

Because the case of the MBR1635 is electrically hot, you must use the necessary TO-220 mounting hardware. If you don't choose this route, then insulate the heat sink from the rest of the project. Of course, you may use a different type of blocking diode for the project. I used a DO-40 stud mount diode in one of the prototypes. I mounted this diode, as well as four IRFZ40 power MOSFETs, to a 4" x 6" x 1/8" aluminum sheet. Since the case of the diode and the drain of the MOSFET are connected by the same heat sink, the entire heat sink had to be isolated from the rest of the circuitry. Although this makes it harder to mount the heat sink, it also makes it much easier to connect the blocking diode and the FETs. With the arrangement mentioned above, I have a current capacity of 45 amps!

That's about all the space I have for this project this month. Next month we'll look at a classic transmitter with a few new touches added. After I correct the final PC boards I'll pick up again with the solar charger.

Super RIT Update

I received word from Rulon Vandyke KA7BCD on a correction for the article "Super RIT for the HW-8." This modification first appeared in the

April 1990 issue of the QRP Quarterly.

There seems to be an error in one of the resistors controlling the bias on a transistor switch. With the values shown in the original, you'll not be able to get the circuit to operate.

The transistor bias resistor R6 should be a 330k-ohm one instead of the crippling 3.3k-ohm one indicated in the schematic and parts list. Proper transmit bias voltages cannot be achieved at the collector of Q1 with such a low value of base resistance. This low resistance changes the R3VR2 voltage divider ratio by effectively adding a low resistance in parallel with VR2.

Since this circuit appeared in many different publications, including the *HW-8 Handbook*, Rulon asked me to let the readers of the "QRP" column in on this correction. So, tell your friends and fellow HW-8 modifiers about this correction to the Super RIT for the HW-8.

Dayton '93 Hamvention

There is some good news and some bad news concerning the QRP get-together this year at Dayton. First, the bad news is that the Knights Inn is no longer in business. Hard economic times did the hotel in. The good news is that we have a block of 50 rooms at the Day's Inn South! This is the same place the QRP ARCI held their first Dayton meeting. Like the buzzards coming home to roost in Hinkley, we've come home.

The room rate is \$75 per night (that's with our discount because the club has a 50-room block). There is no restriction on the number of people you can have in the room.

If you want to stay with the QRP ARCI this Dayton '93, drop a note to Myron Koyle N8DHT at 1101 Miles Avenue, Canton OH 44710, or call him at (216) 477-5717 for more information. You'll need to send in a check for one night's stay (\$75) and make the check out to Day's Inn Dayton South. Hope to see you there!

TNT Today's No-Tune Multiband Antenna

No pruning
TNT is No-tune on 80, 40, 20, 17, 12, 10, 8, 6, 5, 4, 3, 2, 1.7 MHz. Works on other bands w/ tuner. DX & Gain rise w/ frequency. Ready to Use. Includes isolation balun & 99 ft RG8. The modern cost-cut version of the classic off-center fed window. Technician \$29.95, General \$34.95.

No tuning
No knobs to twist. TNT/2 is No-tune on 40, 20, 10. Work other bands w/ tuner. DX & Gain rise w/ frequency. Kink-proof. Wx-Sealed. Low Noise.

No Traps or Resistors
Insulated to 3000 V. Rated 500 Watts.

TNT \$89.95 - \$8 P&H
Window 135ft. long

TNT/2 \$79.95 - \$7 P&H
Window 67 ft. long

Radio Direction Finding

Joe Moell, P.E., KØOV
P.O. Box 2508
Fullerton CA 92633

Denver Hams "Excel" at T-Hunting

Portable computer technology is astounding. Isn't it? My first, a Sinclair ZX-80, amazed me. But it seems primitive next to today's laptops and notebooks. Unless you already have one of the newest of these little marvels, I'll bet you're looking for a good excuse to acquire one.

If your ham radio activities include radio direction finding (RDF), you can put your laptop to work. My last two columns told you how WB8WFK uses one to get more accurate bearings on hidden transmitter hunts, sometimes called foxhunts or T-hunts. This month we'll move on to some new ideas in computerized triangulation.

Trigonometry Without Tears

Competitive mobile T-hunts pit individuals or teams against one another. Rules forbid collaboration between teams and assistance from base stations. Clues of any kind are a big no-no.

However, there are times when RDFers can and should work together. Search and rescue hunts go faster when the participants share information. It's much easier to pinpoint a jammer or bootlegger when several widely scattered teams com-

pare their bearings.

From a single location, you can determine the azimuth of an incoming signal with fair accuracy, but you can only guess the distance, based on the strength of the signal. When azimuth information is available from two or more properly-spaced locations, the intersection of the lines of bearing tells not only the direction of the T but the distance to it. The process of determining this intersection is called "triangulation." Since this term comes from the word "triangle," you might get the idea that three stations or bearing-taking locations are required. Actually, only two are needed. Two lines of bearing plus a line drawn between the stations forms a triangle. In addition, right triangles are created when you intersect the bearing lines with north-south and east-west grid lines.

If bearings are accurately taken and the signal has followed a direct path to the observer, the intersection will be the location of the signal source. Of course, conditions are seldom ideal. Buildings, hills and mountains reflect VHF signals, causing bearing inaccuracies.

The pattern of an RDF beam or quad can be skewed, due to non-symmetrical construction. It can be affected by the vehicle or nearby objects. Your compass reading can be thrown off by a local magnetic disturbance as you sight along your antenna boom for a bearing.

To counteract these effects, it's

Photo A. Tim Mofitt NØNXI (left) and Paul Temlund WB3JZV use a Macintosh PowerBook computer for triangulating. They live near Denver, so they are used to T-hunting in cold weather. (Photo by Stephen Temlund.)

best to take lots of bearings, perform lots of triangulations, and average the results, throwing out the wildest of the individual fixes.

The usual procedure for triangulation involves drawing lines on a map using a protractor and straightedge. You can cross two lines on a map quickly, but when there are many reporting stations and many bearings the map becomes a confusing jumble of points and lines. Here's where digital technology can speed things up and improve accuracy.

In recent years several hams, including WD8CBE, N6JSX, and yours truly, have written RDF programs for various computers. They feature triangulation from stations at pre-programmed locations, telling the user how far he is from the predicted T-location, plus which way and how far to drive to get there.

Listings for two such programs (DF2.BAS and DF3.BAS), along with a detailed explanation of triangulation theory and equations, are in Chapter

20 of the book *Transmitter Hunting—Radio Direction Finding Simplified* by KØOV and WB6UZZ, available from Uncle Wayne's Bookstore. The programs are in BASIC-80 and can be readily adapted to almost any computer, even my old ZX-80.

Don Lewis KF6GQ has written a special program for cooperative hunts in Southern California. It runs on PCs with VGA graphics and includes a built-in map of the Los Angeles region in the display. Send an SASE to Don (543 Bradbury Road, Monrovia CA 91016) for more information on THUNT91A.EXE.

Something New from the Mile-High City

Most RDF programs declare the hidden transmitter's location one fix at a time. What happens when there are three, four, or a dozen stations taking bearings from scattered locations at once? If you triangulate them all, two at a time, you will get many different fixes, due to inaccuracies in each bearing. Which fix is best?

In the T-hunt book, I mentioned that an advanced RDF program could average the results of multiple bearings to give a refined estimate of the T's location. It could also compare the performance of each bearing-taker, based on this result. KF6GQ's program can average up to 10 bearings at a

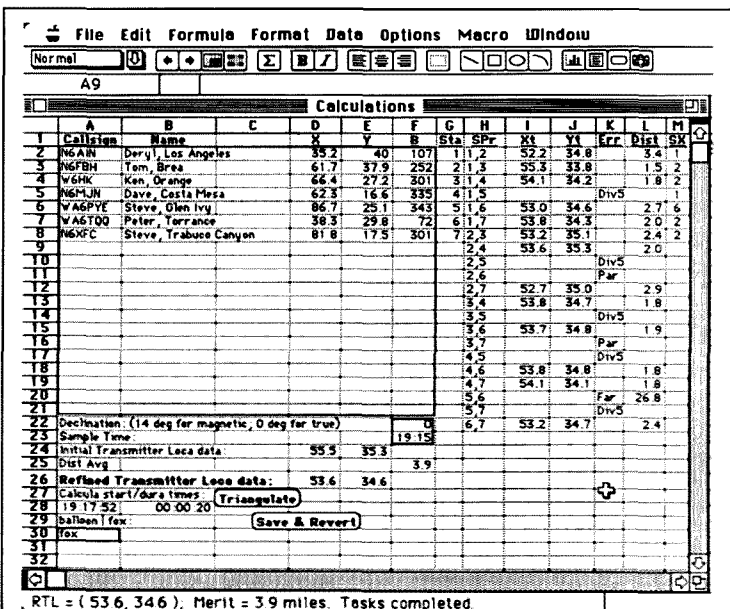

Figure 1. Bearing and location data is typed into the bordered area of the Calculations spreadsheet (cells A2 through F21). The computer triangulates the bearings in pairs and displays the results in other cells.

time, but it is limited to the Los Angeles area.

A more general program with many additional features has been developed by Paul Ternlund WB3JZV. He is an engineer and computer scientist with the Department of Defense, living in Aurora, Colorado. His favorite ham radio activities include foxhunting and tracking ATV balloons.

"I'm a nut for accurate bearings," Paul says. "I'm trying to get a practical understanding of 2 meter bearing-taking and all the phenomena that go with it. When I'm the fox on Denver's competitive hunts I ask hunters to give their bearings to me as they hunt, and I give bonus points for the best ones." A program for calculating and displaying multiple bearings must have fast math functions, sophisticated plotting routines, and a tabular user interface. Paul's T-hunt partner, Tim Moffitt N0NXI, suggested using Microsoft® Excel instead of creating a complete executable application.

Paul wrote a set of macros that accept bearing data from up to 20 RDFers, triangulate each pair, detect and throw away "wild" fixes, average the good fixes to give a best guess of the T's location, and more. The results appear in just a few seconds on a PowerBook or other Macintosh computer. (The routines should also work on the PC version of Excel, but Paul has not verified this.) WB3JZV's algorithm deduces the predicted T location using double averaging. To show how it weeds out the bad bearings, let's go through a hypothetical cooperative hunt. Assume that it's just after dinner time and a continuous carrier has appeared on a popular packet frequency in the Los Angeles basin, blocking all message forwarding.

Another Stuck TNC

Several T-hunters get together on a voice repeater. All have a good direct signal from the QRMing station at their homes except for WA6PYE. Steve's house is blocked from the signal source by the Chino Hills and the Santa Ana Mountains. He doesn't realize it, but the signal is getting to him by reflecting off Mount Baldy in the San Gabriel Mountains to his northwest.

Each station reports antenna heading in degrees azimuth and location, given as coordinates on an agreed-upon map. This group uses the AAA Los Angeles County and Vicinity map, marked with a grid of one-mile squares. The one-mile lines are numbered in ascending order to the north and east, beginning with zero in the lower left corner.

You are the search coordinator, so you start Excel and load Fast-Workspace to begin the triangulation process. This opens the Calculations spreadsheet (Figure 1) and some other files that will be described later. You type in the callsign, name and

Figure 2. After triangulations are complete, WB3JZV's program produces an Excel chart of the hunters and their fixes on the fox. In this case, the final position estimate is almost buried under them. I drew in the coastline (solid) and major freeways (dashed) for reference.

city (optional), location coordinates (X and Y), and bearing (B) for each reporting station. A mouse-click of the Triangulate button near the bottom of the spreadsheet starts the computations.

First the program assigns each station a number, shown in the "Sta" column. Then it triangulates each pair of bearings and displays the outcomes in the "SPr," "Xt," and "Yt" columns. W6HK and N6XFC each gave a bearing of 301 degrees. Parallel bearings do not intersect, so the program puts "Par" in the error ("Err") column for station pair 2,6.

Bearings of WA6TQQ and N6FBH differ by exactly 180 degrees; thus bearing pair 3,7 cannot be triangulated and a "Par" error is displayed. WA6PYE's reflected bearing diverges from bearings of all stations except WA6TQQ. The program displays a "Div" error in these cases.

The macro averages the "Xt" and "Yt" values of all fixes to give a preliminary position estimate. Then it calculates the distances from this preliminary position to each of the fixes, displaying them in the "Dist" column. Next it scans the distances, looking for fixes that are at greater-than-average distance from the preliminary position estimate. In this case, the intersection of WA6PYE's Baldy bounce bearing with WA6TQQ's bearing was almost 27 miles away from the main cluster, so the program discards this fix and displays a "Far" error for pair 5,6.

The macro averages the surviving fixes to get a final position estimate, which it displays in line 26 and the status bar at the bottom of the window. You mark this point on the AAA map to see where it is.

Meanwhile, Excel generates a scatter chart showing the hunters, the surviving fixes, and the final posi-

GLOSSARY

Azimuth—Astronomical term for angular degrees measured in a clockwise direction from true north. For example, east is azimuth 90 degrees.

Bearing—In RDF, the compass direction of an incoming radio signal as observed by a receiving station. True bearings are taken in degrees relative to true north, while magnetic bearings are relative to the earth's magnetic North Pole.

Triangulation—RDF technique for determining the position of an unknown emitter by trigonometry, using bearings taken from two or more known locations.

Fix—The position determined by triangulation from bearings taken at two points.

Spreadsheet—A grid of cells containing numbers, formulas, and labels (see Figure 1). Spreadsheet computer programs such as Microsoft® Excel are used to enter data, calculate results, and display in tabular and graphic form.

Macro—A computer file containing a set of formulas to direct a sequence of actions, such as choosing commands, entering formulas, and performing calculations. Excel uses macros to carry out complex operations on data in spreadsheets.

tion estimate (Figure 2). Excel automatically selects the area of display and scales of the X and Y axes, but you can change them manually if you wish.

Let's Roll

MacroFast has reduced the search zone for our hypothetical stuck carrier to a small area just northwest of the intersection of Carmenita and Rosecrans in the city of Santa Fe Springs. That's the best estimate we can expect from triangulation methods when the nearest RDFer is over eight miles away. Now it's time to send in the mobiles.

From Figure 2, it's clear that the fastest way to end the QRM will be to phone T-hunters in the connecting cities of Santa Fe Springs, Norwalk, and Downey. If none are available, and a choice must be made from stations in this RDF net, it looks like W6HK can get to the

scene fastest. He is farther away than N6FBH, but he is close to a freeway that goes directly toward the target intersection.

Although not needed in this case, you can quickly update the position estimate when additional observers check in. Just add the next bearing on row 9 of the Calculations spreadsheet, click the Triangulate button again, and MacroFast will recalculate and redisplay the scatter chart. The program can crunch up to 20 bearing reports at a time.

WB3JZV's file set is excellent for coordinating the search for a stuck transmitter or jammer, but Paul designed it for a more ambitious purpose—recovering ATV balloons. Next month's "Homing In" column will show you how the system tracks moving signals, develops a figure of merit for the position estimate, and grades the performance of each hunter.

Understanding Asynchronous Communications

It will come as no surprise that the most common roadblock to setting up a packet station is making the connections among the components. The connection between the radio and TNC (Terminal Node Controller), and from the TNC to the terminal, can have you pulling your hair out if they don't work as expected. This month we'll take a look at the TNC-to-computer link (Part 1 of 3). The series will cover both communications hardware and software. I will focus on the IBM-PC because that is the overwhelming choice for use in ham radio. If you don't use a PC, don't stop reading—the principles discussed are true of all computers/terminals, only some details will be different.

All Your Bits in a Row

The communication between your TNC and terminal is called a *serial* connection. It gets its name from the way the data is transmitted. The fundamental particle of data is called a *bit*. Bits can have one of only two values: 0 or 1. In a manner not unlike Morse code, bits are transmitted in groups, each distinct group assigned a value. For example, in the most commonly used code—called ASCII, for American Standard Code for Information Interchange—the string of bits:

1100101

stands for a lower case "e." The serial connection between the TNC and terminal sends one bit at a time—serially—and so gets its name from this behavior. The alternative to this is called parallel data transmission. This technique is faster because it uses more than one data line to transmit the information. Each bit in the code gets its own data line and the entire code can be sent in one move. The most common place to find this technique is printer connections. The Centronics parallel interface is the standard in the PC world and, because of this, on many other computers as well. Most parallel connections have eight data lines, and so are able to pass data eight bits—called a byte—at a time. This is because most communications codes use the byte as the basic character size. There are exceptions to this. For example, because of the large number of characters, Japanese codes use 16 bits (two bytes) to get more combinations.

Some programs which use the parallel port for bidirectional communications—such as file transfer programs like Lap-Link—overcome the unidirectional nature of most PC parallel ports by transmitting the data on the printer status lines. These are the connections the printer uses to say it is ready,

or out of paper. Because there are only four of these, data is sent a *nybble* at a time. Yes, you guessed it, a nybble is a half-byte (4 bits).

RS-232D

The serial port on your PC follows a standard called RS-232D. This standard describes the signal lines, and to which connector pin they are assigned. Strangely, it does not specify a connector type, but the 25-pin D connector is the de facto standard. There are 25 defined pins in the RS-232 standard. Amazingly enough, you may only need three of them.

The three workhorse pins in the RS-232 connector are:

- 2 (TD) Transmit Data
- 3 (RD) Receive Data
- 7 (SG) Signal Ground

As you can see from the list, an RS-232 connection can be very simple: someplace to send the data, someplace to get the data, and a common ground. If this works, why bother with 25 pins?

Handshaking

In a perfect world, the receiver would be ready to receive whenever the sender was ready to send. Your own real-world experience will tell you, though, that the word "standby" is very useful. Digital communications is no different, and it is often the case that the data flow must be interrupted. This is called *flow control* or *handshaking*. The RS-232 spec defines several status lines that are variously used for "hardware" handshaking:

- 4 (RTS) Request to Send
- 5 (CTS) Clear to Send
- 6 (DSR) Data Set Ready
- 8 (DCD) Data Carrier Detect
- 20 (DTR) Data Terminal Ready

These handshaking lines can be used in many ways, but the most common is the RTS/CTS combination. But what about our three-wire setup?

The three-wire connection provides only enough wires to get data to and from the terminal and DCE. This means that handshaking must take the form of *software flow control*. The standard form of software flow control is called XON/XOFF protocol. To understand why, and how it works, we have to take a look at ASCII code again.

When transmitting data, it is often necessary to send some information concerning the connection itself. In the case of flow control, we want to stop and start the data stream. How can we do this? Well, we could send STOP! every time we wanted to stop it, and START! to get it going again. The trouble with this approach becomes apparent when we decide to send STOP! or START! as part of the message text itself. Well, you say, I'll probably never want to send that anyway, so I'll just "reserve" it as a command. You can't send it as part of a message, and

that's that.

Well, this would work, but it would be very cumbersome. If we get a little clever we can reserve a single character, say "\." Then if "\." appears in the data stream, whatever follows should be interpreted as a command. This technique is known as an *escape* character, and is actually used, though not for flow control. While either of these techniques could get the job done, the designers of ASCII came up with a more transparent scheme. They reserved the first 31 codes as *control characters*. Yup, these are the codes that are generated when you hold down the control key and type a character. These characters need never be part of the text, and so can be immediately interpreted.

Each of the control characters has a name and function. Some of them have fallen into disuse, but there are a few of interest:

Character	ASCII	Function
CTRL+G	07	BEL (rings terminal bell)
CTRL+H	08	BS (backspace)
CTRL+I	09	HT (tab—the H is for horizontal)
CTRL+J	10	LF (line feed)
CTRL+L	12	FF (form feed—clears the screen)
CTRL+M	13	CR (carriage return)
CTRL+Q	17	XON (starts data flow—also called DC1)
CTRL+S	19	XOFF (stops data flow—also called DC3)

As you can see, most of the control characters perform familiar functions. You are probably used to hitting the backspace key to backspace, but you can experiment with CTRL+H—you'll see that it works. The last two are the flow control characters. They are generically known as DC1 and DC3—DC means Device Control. When your terminal needs to stop the data flow it sends CTRL+S to the DCE; to start it back up just takes a CTRL+Q. You can even do this manually.

Who's Who?

As you may have noticed, the RS-232 spec has a "point of view." That is, the connections are defined with one side as receiver and the other as sender. Of course, it is quite unusual to have a one-way data circuit—so what's the deal?

The individual data lines in RS-232 are not bidirectional—notice that there are separate send and receive lines. They are also complimentary—inputs must be matched to outputs. This leads to classes of equipment. Your computer or terminal is called DTE (for Data Terminal Equipment) while your TNC is known as DCE (for Data Circuit Terminating Equipment). The RS-232 spec is written from the DTE point of view.

Usually equipment to be connected to a data terminal—be it a computer or dumb terminal—such as a modem, TNC, or serial printer, is configured as DCE. This is not always the case, and is why there is such a thing as a *null modem cable*. A null modem cable

flips the complimentary lines over so the two like devices (DCE-to-DCE, or DTE-to-DTE) can communicate. In the practical world of packet stations, a standard modem cable—sometimes called a Hayes modem cable, after the company that pioneered telephone modems for PCs—does the job. This cable is wired to connect DTE to DCE, the "normal" case.

Technology Marches On . . .

The IBM-PC had a 25-pin D connector for serial communications, but only used nine of the pins (maximum) to make a connection. It didn't take long for IBM to decide this was a waste of pins, so with the introduction of the IBM-AT the connector was changed to a 9-pin D connector. While this was a good idea, the implementation left something to be desired. The nine pins—as defined by the RS-232 standard—used by an IBM serial port are 2,3,4,5,6,7,8,20, and 22. Now, it would seem obvious—at least to me—that the best course would be to leave pins 2 through 8 assigned to the respective pins on the DB-9 connector. I must be missing something, or maybe that was just too simple, because here is what IBM came up with:

DB9	DB25	Designation
1	8	DCD (Data Carrier Detect)
2	2	RD (Receive Data)
3	3	TD (Transmit Data)
4	20	DTR (Data Terminal Ready)
5	7	SG (Signal Ground)
6	6	DSR (Data Set Ready)
7	4	RTS (Request To Send)
8	5	CTS (Clear To Send)
9	22	RI (Ring Indicator)

This may be confusing, but we are stuck with it. In any case, as long as you know the pinout you can make a working cable—the signals are the same.

Why Asynchronous?

You have probably heard the term before, maybe in its shortened form of "async," but what does it mean? Async refers to the fact that characters sent over the connection will not necessarily arrive at any particular time. This is important because the receive station must somehow decode the incoming signal, and to do that it needs to know when the character starts and ends. This is where the notion of start and stop bits comes from. These allow the receiving equipment to determine the front and back of the transmitted characters. When you set your communications parameters to:

- 8 data bits
- no parity
- 1 stop bit

you are specifying the structure of each character sent. One stop bit will be sent—a start bit is always sent. The parity bit is used—or rather not used—for error detection. Though this is its intended purpose, it is rarely done.

I am going to stop here with Part 1. Part 2, next month, will finish this discussion—with the final installment cov-

DEALER DIRECTORY

DELAWARE New Castle

Factory authorized dealer! Yaesu, ICOM, Kenwood, Ten-Tec, AEA, Kantronics, DRSI Mfg., Ameritron, Cushcraft, HyGain, Heil Sound, Standard Amateur Radio, MFJ, Hustler, Diamond, Bulternut, Astron, Larsen, and much more. **DELAWARE AMATEUR SUPPLY, 71 Meadow Road, New Castle DE 19720. (302) 328-7728.**

NEW JERSEY Lodi

North Jersey's newest Two Way Radio and Electronics Dealer is now open. Sales of Ham, Business, Marine and C.B. two way equipment as well as Scanners, Shortwave, Electronic Kits, Antennas, Books, Cable Boxes and more. Friendly service and low prices. **Advanced Specialties, 114 Essex Street, Lodi NJ 07644. (201) VHF-2067.**

Park Ridge

North Jersey's oldest and finest Shortwave and Ham Radio Dealer. 1 1/2 miles from Garden State Parkway. Authorized Dealers for AEA, Kenwood, Japan Radio Company, ICOM, Yaesu, etc. Ham Sales, Lee WK2T. **GILFER SHORT-WAVE, 522 Park Ave., Park Ridge NJ 07656. (201) 391-7887.**

NEW YORK Manhattan

Manhattan's largest and only ham and business Radio Store. Featuring MOTOROLA, ICOM, KENWOOD, YAESU, UNIDEN BENDIX-KING,

DEALERS: Your company name and message can contain up to 50 words for as little as \$420 yearly (prepaid), or \$210 for six months (prepaid). No mention of mail-order business please. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the April '92 issue must be in our hands by February 1st. Mail to 73 Amateur Radio Today, 70 Rte. 202 N, Peterborough, NH 03458.

ASTRON, AEA, SONY, PANASONIC, MFJ, CCTV CAMERAS AND MONITORS, BIRD WATTMETERS, OPTOELECTRONICS FREQUENCY COUNTERS, AOR SCANNERS, JRC RECEIVERS, KANTRONICS, LARSEN, etc. Full stock of radios and accessories. Repair lab on premises. Open 7 days M-F, 9-6 p.m.; Sat. & Sun., 10-5 p.m. We ship Worldwide. For specific information call or write: **BARRY ELECTRONICS, 512 Broadway, New York NY 10012. (212) 925-7000. FAX (212) 925-7001.**

OHIO Columbus

Central Ohio's full-line authorized dealer for Kenwood, ICOM, Yaesu, Alinco, Japan Radio, Standard, AEA, Cushcraft, Hustler, Diamond and MFJ. New and used equipment on display and operational in our new 10,000 sq. ft. facility. Large SWL Department, too. **UNIVERSAL RADIO, 6830 Americana Pkwy., Reynoldsburg (Columbus) OH 43068. (614) 866-4267.**

PENNSYLVANIA Trevose

Authorized factory sales and service. KENWOOD, ICOM, YAESU, featuring AMERITRON, B&W, MFJ, HYGAIN, KLM, CUSHCRAFT, HUSTLER, KANTRONICS, AEA, VIBROPLEX, HEIL, CALLBOOK, ARRL Publications, and much more. **HAMTRONICS, INC., 4033 Brownsville Road, Trevose PA 19047. ering software following that.

Survey Results

A couple of months ago I included a survey in the column. I have gotten quite a few responses (thanks to all who took the time), but I want to see if I can get more. So, those of you waiting breathlessly for the results of the survey—take a breath. To tease a little: You guys are overwhelmingly PC users, quite a few of you with heavy-duty machines! There is a strong interest in Internet connectivity, and in improved software for packet use. After more readers respond I will publish the results here. Below are the questions once again. Paper mail and email are both fine.

1. What is your callsign?
2. What is your license class?
3. What computer(s) do you use in the shack?
4. What operating system/environment version(s) do you use?
5. Which digital modes are you equipped for?
6. Which digital modes are you active in?
7. Which of these columns (month, year) has been your favorite (if any)?
8. What has been your biggest problem with computers in ham radio?
9. What would you like to see in this column?
10. Any comments:

You don't need to copy the questions, just put the number before your answer. Answer all the questions, or just the

ones you want. Make the responses wordy or brief. I really want your feedback to make this column something you look forward to each month. Thanks so much for your participation.

Electronic Addresses

Packet: N1EWO@NOARY

(note: I'd love to hear from you on packet—but not about the survey! This survey is the business of this magazine, and we can't do that on ham radio. A personal note or test message is just fine.)

Internet: jsloman@mcimail.com

(This is my preferred address.)

MCI Mail: jsloman

(This is the same as above, but direct.)

CompuServe: 71221,1143

(This is my least favorite place to get mail, but it is OK.)

Even if you don't answer any survey questions, I am very interested in anything you have to say. I can't answer every message—though email has a *much* better chance. Many of you have written asking for help. You have not been forgotten—I am planning a "mailbag" column for the near future where I can answer the many similar questions that come in. For those of you who have written saying that you enjoy the column, thanks. For those of you who would like to see additions/changes, please write to me—it's the only way I have of knowing what you need and want. 'Til next month, 73 de N1EWO.

RF Actuated Coaxial Switching

My desire for a coaxial switching circuit that would activate on the presence of very low level RF from low power SSB HTs started me off on a new project. This is the circuit that I mentioned last month in the narrative covering mobile operation on 10 GHz. This circuit was the output of a design effort to permit our 10 GHz converters to be switched on RF detection from the transmit IF, our 2 meter SSB HTs. These HTs have a low power output of about 100 mW. The circuit can be easily modified to accommodate higher power transceivers. More on that later.

The development of this unit was predicated on a coaxial switching system that operates on RF carrier detection, eliminating the need for manual RF switching. This manual switching involved multiple switching circuits controlling converters, preamplifiers, IF switching, and other switching relays that inserted the high power TWT amp on transmit. The addition of this new control circuitry would make our microwave rigs push-to-talk, a great improvement.

This switching system is not limited to low power configurations or to microwave operation. It can be adapted as you wish (it's a basic control circuit, not just for microwave) to handle higher powers and lower microwave frequencies. As a matter of fact, you could use it to control VHF converters as easily as my microwave systems. It is well-suited to custom installations and adaptable to various switching needs.

The Circuit

First, let's get into the circuit. It's quite simple and it evolved from several designs used for transmitter-actuated switched circuits, or "tranx" switch circuits. Some of the basic tranx circuits consist of a simple diode detector rectifying a small portion of the incoming RF to produce a controlling DC signal for control use. This DC voltage is usually applied to a Darlington transistor providing high gain and amplification, allowing a relay connected in its output to be activated on detection of transmit RF. See Figure 1.

This circuit does work, but has some limitations. One limitation is that most RF detection circuits assume you have a transmitter power of a few watts or so, allowing easy brute force detection to actuate the control circuit. Delicate operation is not one of its

traits. When we use a 2 meter transceiver as an IF system in our microwave converters, the higher powers are a detriment. This doesn't mean that they can't be used, but the extra power serves no purpose. If a higher power radio is used, most of the power output must be dissipated before being applied to any converter. Usually radios that provide 100 mW are desirable for converters as they will operate for long periods of time without requiring large battery packs.

In tests that I conducted, Darlington circuits proved to be very unreliable when switching multiple circuits in tests that I conducted. What was needed was a very sensitive circuit that would be reliable and not give false operations. A search through many pieces of literature produced many different approaches, but never seemed to hit the mark I wanted.

Part of the answer came from the *RSGB VHF Handbook*, fourth edition, chapter 6.3. They described just what we wanted: an op-amp-controlled, very sensitive RF-actuated detection circuit using two diodes and a 741 op amp. I built the circuit and was very impressed with its operation. It was so sensitive it would operate on key-up SSB without modulating the rig. I tried to make the circuit false (fail) but it operated very reliably. I was pleased with its high sensitivity and its ability to operate the keying circuit on SSB PTT without requiring modulation.

Improving the Circuit

The basic circuit designed by the RSGB group had one flaw: a switching transistor that is used for relay control. Up to this point I was looking at the output of the op amp for test results. This book was published in 1983 and the improvement I made was to incorporate components that were not available or were very expensive at that time.

The change or improvement is to replace the transistor with a power FET. This simple improvement made all the difference in the world in circuit operation. It speeded up switching times and made the circuit very easy to duplicate as the op amp can drive a FET easily. I used an "N" channel FET so that when the op amp did not detect RF its output would be negative,

or, switched towards the source of the FET, turning it hard off. When the op amp pin #3 went positive on RF detection its output would switch towards the positive rail, turning the FET's gate positive and on (see Figure 2).

The difference between a transistor and an FET in switching times is like comparing a Model T Ford to a Ferrari. The FET and Ferrari are both very fast. As a matter of fact, the FET can switch in the nanoseconds, something the transistor can't accomplish.

Now the switching and RF detection circuit were functioning well. The remaining circuitry that needed to be designed was the control switching and delay for the coaxial relays. This part of the circuit would do the actual control or receive and transmit switching and timing for our microwave converters. What we desired was some time control or delay to allow the RF preamplifier switching to take place prior to the key-up of the transmitter power amplifier, a 10 watt TWT. We wanted protection during the preamplifier's switching, and to allow that to be done first. Then, in sequence, we wanted the transmit circuits to be switched into place, preparing the converter for a transmit function. This protects the receive preamp during transmit. (By the way, this same preamp is used as the transmit preamp during transmitting.)

Conversely, when we released our push-to-talk circuit (return to receive from transmit), we wanted the high level switching to de-activate first, turning off the high power amplifier and removing its coaxial from the circuit. Then, after a timing delay, we wanted the low level circuit to return to its normal receive configuration. This prevents the 10 watt TWT power amplifier from coupling any energy into receiver circuits. There is a chance of destroying the low-noise receiver's front end from transmitter coupling with switching errors.

The problem is that we wanted a complex switching circuit with minimum components. Sounds kind of unobtainable, but Kerry N6I2W came up with a very simple circuit to handle it. We used it in both our 10 GHz rigs during the last weekend of the ARRL 10 GHz contest and it worked superbly.

The time delay circuit retained the fast switching of the FET from the original op amp circuit and incorporated a simple RC time constant network with diode steering to accomplish the switching timing needed. A single 4049 hex inverter was used to interface the op amp and FET switching circuit. This portion of the circuit uses diodes for fast turn-on, providing a rapid DC charge of the timing capacitor. There's no RC time constant involved here; it's bypassed by the diode. When the control circuit (PTT) is released, the DC voltage of the op amp reverts towards negative and the charge on the capacitor, shunted by the 1 megohm resistor, forms the first timing circuit, with a delay hang oper-

Figure 1. Basic RF switching circuit.

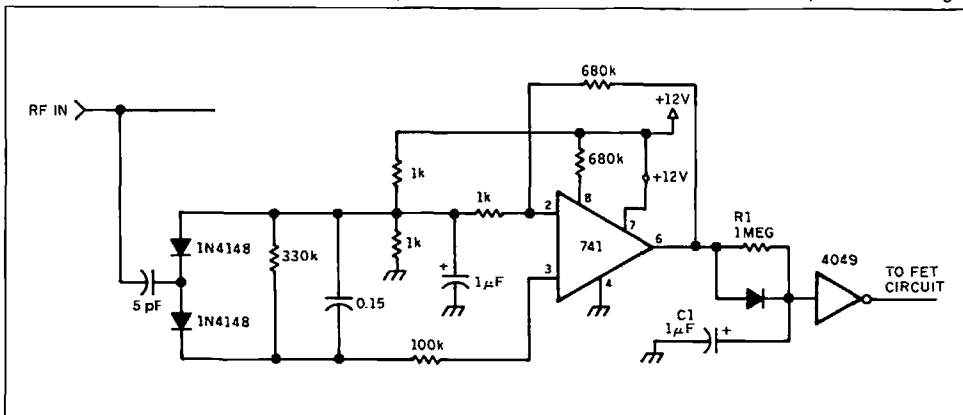

Figure 2. Sensitive RF circuit for SSB.

ation of about a second or so.

In the release cycle (receive), this circuit provides a one-second time constant. The diode is effectively out of the circuit at this time. This release time constant is sufficient to hold the circuit operational between SSB modulations, to prevent premature release of the keying relays. If you want a longer time, increase the capacitor value. Adding an additional 1 μ F capacitor (now 2 μ F total) gives a two-second hold time.

Two FETs were used in our circuit: one for the receive circuits and the other for the transmit circuits. The speed of operation for each circuit is determined by the R/C time constants on the FET's inputs. The hold time or hang time after releasing is controlled by diode steering of the exact opposite timing to the other FET's gate circuit, accomplished by the RC charging time constants of a 1k resistor and 1 μ F capacitor vs. a 47k resistor and 1 μ F capacitor. That controls the key-up time control. For the circuit to meet design constraints, the exact reverse of each circuit is needed. This was accomplished by using diode logic to take the voltage available on the opposite charged capacitor to control the other FET's gate. See Figure 3, the FET switching delay circuit.

The switching relays used for control were connected to ground in each of the two FET source leads. The drains were tied to Vcc (+12 volts). As long as the op amp is off (no RF detected), the relays are in a released condition. The relays used for control voltage are not special relays. A suitable relay for 12 volt operation can be purchased from Radio Shack (PN 275-217; \$5.99 each). Any low current 12 volt multicontact relay can be substituted and should work well. I scrounged my relays off of some junk PC boards and saved a few bucks.

How do you unsolder multicontact items from PC boards? Well, get down to your local hardware store and purchase a paint-stripping heat gun. It unsolders better than it strips old paint, and it's inexpensive, less than \$20.

Putting the circuit to use is the custom part of the exercise. I will describe my application, but your circuit will vary, depending on how you switch your rig's elements about. In my transceiver, I switch my preamplifier forward and in reverse, using it for receive and transmit. Additionally, in transmit I switch the now reversed preamp to drive the TWT amplifier to full power output. To accomplish this switching I use a bank of four SPDT coaxial relays. Another relay is used to switch out a direct connection from the mixer IF port to the HT and replace it with a 10 dB attenuator for transmitting. The third switch point is internal to the TWT power supply to transfer it from standby to transmit.

My sequence of events is as follows: I want the four relays to actuate first, along with the IF switching relay. Then and only then do I want the TWT relay to actuate. In this way I

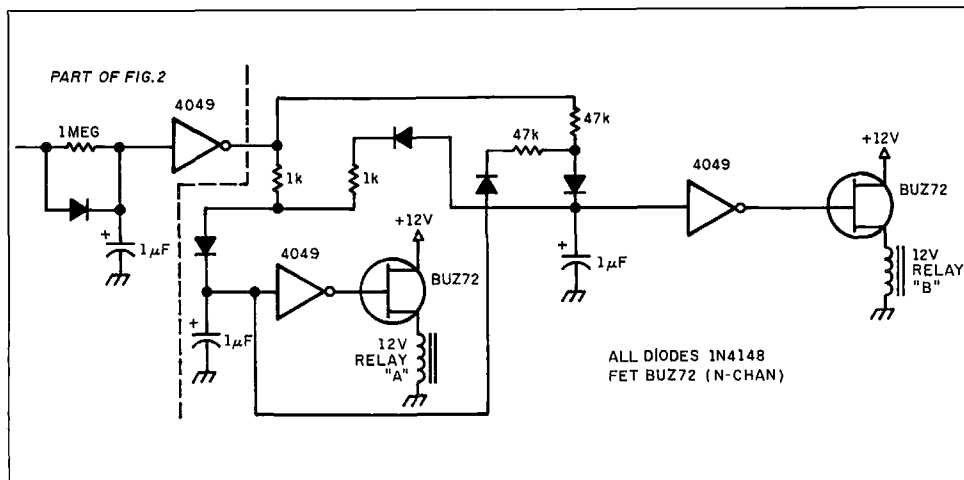

Figure 3. Timed FET switching circuit.

protect the low-noise preamplifier from the transmitter power stages by keying the power amplifier last when going to transmit. In the power down sequence this same relay must release first. This switching sequence will be similar in your situation, depending on what constitutes your elements. In any case, to set up your system's switching requirements, all you need to know is which relay is fast to operate and slow to release. See Figure 4 for the full system schematic diagram.

In actual practice, both our rigs have the circuit constructed dead bug fashion on a scrap piece of copper PC board. The FETs I used were BUZ-72 types, capable of several amps of switching capacity for relay drivers. Quite an overkill, but they should work for quite a while without problems.

I plan to make artwork for this PC board in the future and will put it in the column in another issue.

West Coast VHF/UHF Conference

The West Coast VHF/UHF confer-

ence will be held in Ventura, California, on the weekend of May 12 through 14th, at the Ventura Holiday Inn, 450 East Harbor Boulevard. Planned events include technical talks and vendor exhibits, and a Saturday banquet and Sunday breakfast, both with guest speakers. On Sunday, antenna range capabilities with pattern plots will be calculated. A color plotter will make plots, labeling each with antenna description and 3 dB beamwidth. Coverage will include 2 meters through 10 GHz. The test range, 300 feet long, will be located on top of the parking garage next to the hotel.

The noise figure measurements, a very popular test session, will also have plotting of your VHF and UHF converters and preamps. This is a tradition deep-rooted in the many conferences that have been held over the years. Hewlett Packard will provide the latest noise figure meter, which will be integrated with a computer and a graphics printer. For anyone who intends to bring preamps, standard con-

nectors are a necessity. They should be female SMA, N, BNC or UHF to allow measurements to be made. Please provide clearly marked power terminals that can be test-clipped for the test measurement. I would add, mark the power pins clearly, least you have a 90 dB attenuator.

Registration for the conference is \$15, due by May 7, for pre-registration awards. For information, contact the Ventura County Amateur Radio Club, VCARC PO Box 2103, Oxnard CA 93033, or Steve Noll WA6EJO at (805) 647-4294. For exhibit space, call (805) 264-1978.

As is normal practice, the ARRL will publish the proceedings for the VHF/UHF conference and will make them available at the conference for \$10. After the conference they will be available from the ARRL directly for \$10 plus appropriate shipping.

Well, that's it for this month. As always, I will be glad to answer any questions related to VHF and UHF. For a prompt response please send an SASE. 73 Chuck WB6IGP.

Fixing Walkies

Probably the most common piece of ham equipment today is the 2-meter HT. Especially since the advent of the no-code Technician license, the popularity of walkies has increased. I haven't met very many hams who don't own walkies. So, it seems reasonable that some of those radios are going to have problems. Let's look at the kinds of problems which tend to occur and at what we can do about them.

What a Cad

Nickel-cad, that is. If you've owned your walkie for more than a year or two, chances are you either have had or soon will have trouble with the battery pack. No matter what the industry says, those darned NiCd batteries just don't last very long. By now, everybody knows that you should run the battery all the way down before you charge it up again. But, even if you do that, a year or two is about all you can ask for. I have met hams who had properly working packs more than three years old, but not very many. My own experience has been pretty dismal, despite the fact that I follow all the rules. Is it possible to actually fix a bad battery pack?

Well, sometimes. In fact, I just fixed one in my cordless drill a few weeks ago, and it's still going strong. I've described before how to zap a NiCd cell, but I'll give a brief repeat here for those who missed it.

There are two fixes which have worked for me. For shorted cells, take a DC power supply and charge up an electrolytic capacitor. The cap should be several thousand microfarads or more; a 100-microfarad cap just won't do it. Charge it to 15 volts or so, being careful to ensure that the cap is rated for more than that. Don't forget to watch the polarity. Now, again watching the polarity, connect it across the shorted cell, + to + and - to -. Don't use clip leads, because their resistance can limit the current flow. Just touch the cap's leads to those of the cell. You should get a nice little spark. Disconnect the cap and measure the cell's voltage. If you get anything much above zero, you've done it; the cell should now charge properly. If the cell is still shorted, try again. It took me 10 tries to fix that drill's cell.

For cells which aren't shorted but just won't hold a charge, I've found that a few seconds of high-current charging can sometimes do wonders. By high current, I'm talking about a couple of amps, not 20! A current-limited DC supply works fine. This fix isn't as dramatic as the other one, but it might save your ailing pack.

Neither of these fixes can be done without getting access to the terminals of the bad cell; you can't do this stuff *through* the other cells in a pack.

After you've fixed a bad cell, you must balance all the other cells before you try to recharge the pack. If you don't, the bad cell most likely will fail again very soon. To balance the pack, charge the bad cell to, say, 1 volt. Then, *discharge* all the other ones through a flashlight bulb, one cell at a time, until they all read 1 volt. Reassemble the pack and charge it normally, and it should work fine if the cells are not too far gone.

By the way, most NiCd packs have built-in thermal fuses that are designed to prevent fires in packs which inadvertently get shorted at their terminals, perhaps by keys or coins in a pocket. If the pack has in fact died immediately after experiencing such a short, a new thermal fuse may be all you need. I don't know where you can buy new ones, but perhaps one of you does. If so, please tell me and I'll pass it along. But please don't even consider simply shorting across the fuse and putting the pack back in service. Even small NiCd packs can deliver enough current into a short to cause serious injury. That's why manufacturers always warn you not to put NiCd cells into holders meant for alkalines; the holders have no fuses, because alkalines don't present nearly as much risk.

Insert Here

Sometimes, NiCd cells simply are beyond redemption. And new packs from the manufacturers are awfully expensive. Besides, my experience has been that most manufacturers

use exceptionally poor cells. When a battery pack goes bad six months after you buy the rig, you sure don't want to shell out for another one just like it! Luckily, several aftermarket companies advertise inserts for walkie packs. These are pre-connected cells which fit into your original plastic shell. I tried one in the FNB-17 pack for my Yaesu FT-411 and it worked great! If you can crack the original pack open carefully enough that it can be snapped or glued back together, you would do well to try an insert. Often, soldering is required but, hey, we're hams, right? By the way, the one brand of cells I've had good results with has been Sanyo. I've seen, and in fact own, Sanyo cells that are five years old and have been abused, yet still work fine. I have no idea why theirs are so much better, but I strongly recommend you buy an insert made with them. You'll wind up with a better pack, at about 1/2 to 1/3 the price of a new, original-equipment pack.

Where's the Magnifying Glass?

OK, your walkie is getting power but it still doesn't work right. Walkies are basically no different than other radios, but they do have some unique characteristics which make them a bit harder to work on. The most obvious one is that they are getting awfully *small* these days. Back when the ICOM IC-2AT and Yaesu FT-208R were all the rage, you still could fit your fingers into the case. Nowadays, things have gotten to the point where surface-mounted components and ribbon cables dominate. How do you fix something like that?

Frankly, if the problem is really tough from a physical standpoint, it probably isn't worth the risk to the radio for you to hack at it. For instance, some modern walkies, such as my FT-411, use little "daughterboards" which stand up on a motherboard. Unlike the similar construction used in desktop computers, though, these daughterboards are maybe an inch square, and they're soldered in. If a tiny chip or transistor goes bad on one of them, just getting to it in order to measure the voltage or observe the signal can be a major chore. Even worse, some circuits may be spread out between what's on the daughterboard and some parts on the back side of the motherboard. Do you really want to mess with this?

Well, maybe, maybe not. If the problem is not obvious, it probably would pay to send it in for repair. Luckily, though, most problems are not due to component failure. Because walkies are so portable, they experience far more troubles caused by bad connections, broken or dirty jacks and switches, corrosion and similar environmental factors.

Open Wide

Before you can fix it, of course, you have to get inside the rig! Most of today's walkies pop apart in two halves, with just a few screws holding them together. Usually, you have to remove the plate which holds the bat-

tery contacts on the bottom. Then, remove the screws on the back and the rig should snap open. Do it carefully, though, because the two halves probably are joined by a ribbon cable, and you don't want to damage that, believe me. If there is a ribbon cable, it should have a removable connector on at least one side. Generally, these covers snap up and down. If you need to pull the radio apart farther than the cable will allow, locate the connector. Now, gently pry up (up being toward the cable) the cover, one side at a time, using your fingernail. The cable should come out easily. (Before you remove it, take note of which way it goes in; reassembling it backward can result in disaster.) If it still seems hard, don't pull! Instead, be sure you have disengaged the cover as far as it will go. When you reassemble it later, be sure to insert the cable all the way before snapping the cover closed. I've seen many cases of "failures" caused by improper reassembly of ribbon cable connectors. And, especially when the cable is one of those plastic things with the printed-on conductors, it is all too easy to rip it and ruin it. So, let the fixer beware!

Contact!

If your walkie is behaving erratically, and especially if it's cutting in and out, check the battery contacts. Dirty, bent or worn contacts can cause a

bewildering array of symptoms. If the contacts look OK, check the wiring to the DC power jack, if there is one. If the jack is soldered directly to the board, look at the solder joints. Very often, the stress of plugging in and unplugging the DC plug will cause those joints to crack. If you're not sure, resolder them for good measure. Also, check that the PC board foils are not themselves broken. Just wiggle the jack a little while looking at the foils and it should be obvious if there's a problem. Now and then, the DC jack itself can go bad, especially if the radio is old. If you don't plug DC directly into the walkie, though, it is unlikely that you will have any of these problems.

Walkies usually have fuses between the DC input and the rest of the rig. These sometimes look like tiny glass resistors, while other times they look exactly like regular resistors. What they *don't* look like, of course, are fuses! With the power and battery disconnected, a simple ohmmeter check will tell you if there's any connection from one side to the other. I've seen these tiny fuses blow with no provocation. As with the battery packs, it's important that you replace the fuse, rather than just jumping across it.

Well, we've just scratched the surface of walkie repair, so let's continue next time. Now, let's look at a letter:

Dear Kaboom,

I have a KDK model 2033 mobile rig and it won't transmit or receive. I think the problem is in the final. Where can I get one of these transistors? I've enclosed a drawing of it and the ohmmeter readings between its pins and case. I've looked in every catalog I have and can't locate the part.

Signed,
Finally Quit

Dear Finally,

First of all, that is not a transistor! It is a final amplifier *module* which contains the final transistor and a whole lot of other things. The Toshiba S-AV7 is used in various rigs, and you should be able to get one from KDK or another manufacturer. But I don't think you need one! If it were shorted, it should blow the fuse in the radio's DC line when you pressed transmit, and perhaps even in receive, depending on the radio's design. If it were open, it would kill the transmitter's output, but it shouldn't affect receive at all! Because the radio won't TX or RX, I'd look elsewhere. Lots of other things could be causing this general failure, which is lucky for you because those modules ain't cheap. See if you can figure out why the rig won't receive. Chances are that when you fix that, it'll transmit too. Good luck!

73, and see you all next month. 73

How To Get Started In Packet Radio

Enter the exciting world of packet radio today with *How To Get Started In Packet Radio*. Dave Ingram, K4TWJ, wrote this beginner's guide to packet radio in an easy-to-understand manner. It starts with a non-technical description of packet radio, followed by chapters that include getting started, setting up your station, networks, BBSs, portable and high-frequency operation and even a *Packet Radio Equipment Survey*. There's also an appendix that includes circuits for interfacing equipment. Join the most exciting and rapidly growing area of ham radio today! Order your copy of *How To Get Started In Packet Radio* book for only \$9.95! (plus \$2.00 S&H).

Commodore Interface

A few months ago, I detailed one ham's odyssey of trying to find a usable interface for an old Commodore computer. I received another response, this one from G. H. Doherty VE3BYR, of Barrie, Ontario.

He tells me that Comtech Research, of Custar, Ohio, has an excellent RTTY program for PC compatibles, which is easy to use and can be configured to work with the CP-1 interface with a minimum of trouble. A serial interface is required to use the interface. If there is not one on the unit already, he passes along this tip for adding one, with a bare minimum of parts: Plug a 75154 chip into a socket wired to a 16-pin header, according to the wiring diagram in Figure 1. The header is then plugged into the original U-13 socket in the CP-1.

He says that the CP-1 has excellent filters, and that he has used it

with a Kenwood TS-830 on RTTY with no problems. On his ICOM 765, the gain to the MIC input is a little low and, according to him, AEA suggests that R116 could be reduced to a lower value, but no lower than 560 ohms. Presumably, this is to increase output.

The RTTY-PC Program

The RTTY program referred to is RTTY-PC, Version 1.07, from Comtech Research. According to the literature I have here, it will send or receive Baudot at 60, 66, 75, and 100 wpm; or ASCII at most standard speeds from 110 baud to 9600 baud. The initial display is of received data. A control menu is entered from that screen.

The display itself is a split-screen affair, with transmit and receive data displayed separately. Mode, speed, date, time, and other data are displayed as well. Twelve 1K buffers are available, accessed through the F1 through F12 keys. Even if your computer does not support all 12 function keys, they say that they

have software that will allow you to use all 12 buffers.

The computer can initiate transmit/receive switching, store received material to disk, and do just about anything else you might think is important for a RTTY program to do. All in all, this sounds like a full-functioned program.

Price? According to this sheet, \$29.95 for the program, \$8 for a printed copy of the manual which is on the disk, and \$5 extra if you want the program on a 3.5", 1.44 Mb disk. Shipping and handling adds another \$3 for North American deliveries, \$5.25 elsewhere.

If you're interested, drop them a line at 5220 Milton Road, Custar OH 43511, and ask for the latest pricing and availability. As always, feel free to drop the name "RTTY Loop" in your letter.

Another Model 28

Web Williams KD4CQK, of Myrtle Beach, South Carolina, says that Ralph Brown is not the only one trying to get a Model 28 up and running—he has one also. He says that his machine has a keyboard, reper, printer, and tape reader. To clarify terminology, that would be a Model 28 ASR, standing for Automatic Send Receive. The "KSR" machine is Keyboard Send Receive, and lacks the tape equipment.

Hopefully, the material published last month was of some use to Web. He adds that it appears as though old terminal units have disappeared from the market. He has been trying, without success, to find one. With a PC compatible and MFJ-1278 in the shack, he can operate on RTTY, so it's not the mode he lacks, it's the method!

If someone in his area has a TU to spare (Web is especially looking for a Dovetronics, or HAL ST-6000 or ST-5000), I am sure he would appreciate hearing from you. Information may be sent here as well, and I will forward it down Carolina way. Thanks for the letter, Web.

CompuServe in Hong Kong

I appreciated the message on CompuServe from Ron Koyich VS6BD, whose interest in RTTY dates back to the 1960s, when he even went mobile with a Model 15. Now THAT's something my wife never let me do! In those days, Ron went under the call of VE6AJX. Hmmm, another AJ! That gets you an honorary membership in the club.

He adds that a CompuServe node is now active in Hong Kong. It will be awhile before they will be able to packet/AMTOR to us from there. There's a Hong Kong packet

ALUMINUM TOWERS

repeater going online sometime this year, to be installed and operated by ELARCS (English Language Amateur Radio Communications Society).

Sounds great, Ron. Keep us posted of the progress. I am sure that those of us in more mundane locales can only dream of some of the stuff you must see over there. Thanks for the note.

DSP-12 for Contesting

Another piece of Email was received from Doug Stracener KA5YSY, in Baton Rouge, Louisiana. Doug relates his experiences in the RTTY DX Worldwide contest, in which he used the DSP-12 processor.

Doug writes, "On Friday evening at 0000Z, the start of the contest, I had fired up my trusty Kenwood TS830 on 15 meters and started contesting with great vigor. Enter Mr. Murphy: At 0010Z the 830 went on strike and refused to transmit on 15 meters! This is not good when one is working single band, single op! The real problem was that the 830 has a set of International Radio crystal filters that are extremely selective on RTTY and make contesting possible.

"Enter the ICOM 735, which is my mobile radio. It has no special filtering other than the standard SSB.

The selectivity for RTTY contests is at best poor, so I was wondering what kind of score would be possible, due to all the QRM and my inability to resolve the signals.

"I recently purchased one of the NIR-10 DSP filters built by JPS Communications of Raleigh, North Carolina, for the purpose of killing the white noise present on the OSCAR-13 audio when I am working satellites. In desperation, I quickly cabled the audio input of the DSP-12 to the ICOM and placed the filter in the passband medium and then narrow modes. Oh, what a difference the DSP-12 made! It is superior in all respects to the crystal filtering of the Kenwood setup and allowed me to operate in high ORM environments of the contest without any difficulty. When turning off the DSP-12 by placing it in the bypass mode, the KAM

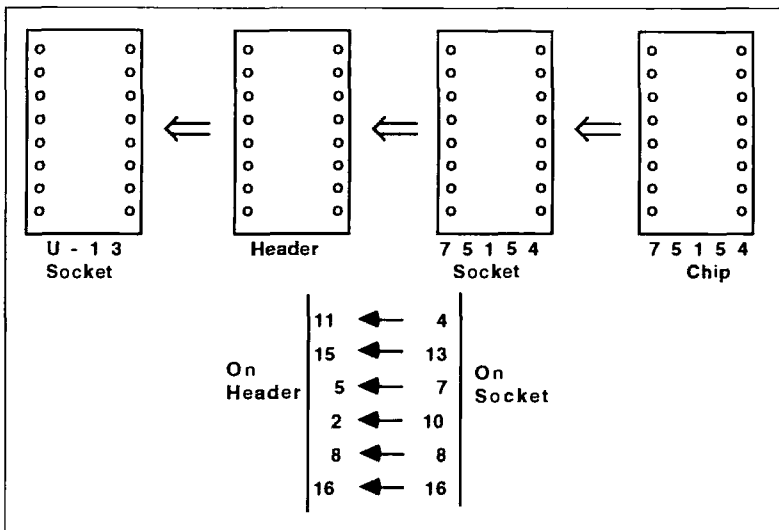

Figure 1. Interface wiring for the CP-1.

TNC I was using was unable to decode any of the multiple RTTY signals within the receiver audio passband.

"Based on the experience I had, I can highly recommend the DSP-12 to any RTTY contest as a piece of equipment well worth the price. On the other hand, maybe you should not tell anyone about this,

and let me keep the secret!"

You don't have to be in Hong Kong to drop me a note. Reach me on CompuServe at ppn 75036.2501; Delphi at username MarcWA3AJR; or America Online at screen name MarcWA3AJR.

Sure, you can write me at the above address as well. Just write, I really do want to hear from you.

QSO Tutor®

Study Aid for the Amateur Radio Exams

Mac IBM

Consider the rest, then buy the best!

New - No-Code Tech. Package!!

- Runs on IBM compatibles or Macintoshes
- Programs are available for Novice, Technician, No-Code Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radiotelephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pools, or study questions automatically selected by the program from your weakest areas.
- Questions current as of October 1992
- Includes full screen graphics, explanations on appropriate questions and, on the IBM version, a pop-up calculator.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or printed with graphics on Epson/IBM or Macintosh printers.
- Public Domain Morse code tutor is included on request at no extra charge.

Computer Control For The Ramsey FTR-146

Build a computer interface for this 2 meter transceiver kit.

by Richard E. Lucka WD8BNR

For a long time I have wanted to use my IBM-compatible personal computer (PC) to control the frequencies of a 2 meter transceiver. I have two Kenwood rigs, but I just don't have the heart to tear these expensive rigs apart to connect them to the computer.

About a year ago, I saw an ad from Ramsey Electronics featuring their FTR-146 2 meter synthesized transceiver. What caught my eye was that the frequencies could be programmed by diodes. I immediately saw the possibility of building an interface to control the rig with my computer, so I ordered a kit.

After building the radio and studying the schematic, I came up with a programmable interface that allows me to program the frequencies using the parallel printer port from my PC. Additionally, I can select the repeater offsets (simplex, +600 and -600) and the +5 kHz channel spacing. I can also "see" the programmed binary inputs to the rig by looking at the LEDs mounted on the interface front panel. Finally, I added a new feature to the rig by tapping into the squelch output pin of the rig's FM detector chip that lets my computer detect the presence of a signal. I added an LED that lights when the rig is receiving a signal.

In this article, I will describe the interface circuit, the cable connections, and a BASIC program that selects frequencies and performs scanning operations on the Ramsey kit.

The Interface

The heart of the rig's tuning capability is the MC145106 digital frequency synthesizer chip. The kit's manual contains an excellent description of how it works and how you can program selected frequencies using a diode matrix. The manual also hints at how you can use DIP switches for selecting your own synthesizer inputs. Beyond that, it's up to you to create another way of programming the frequencies.

The 5106 synthesizer contains nine input pins. Each input may be "on" (+8 volts) or "off" (0 volts). The combination of "on" and "off" inputs determines the frequency you want. The inputs coincide with digital numbers, starting with 1 and ending with 256. In other words, the pins are labeled 1, 2, 4, 8, 16, 32, 64, 128, and 256. If you add up all

Photo A. Parts placement of the interface on a Radio Shack 276-147 board inside an RS 270-274 cabinet. The LEDs are installed on another RS 276-147 (cut in half) and mounted inside the front panel. The circuit on the right side of the board is a packet modem interface, described in "Poor Man's Packet," 73 Amateur Radio Today, August 1991.

the numbers, you get 511 frequency possibilities.

There are a total of 400 channels in the 2 meter band, all spaced 10 kHz apart. The synthesizer can tune an additional 111 channels ($511 - 400 = 111$). If all the input pins are low, the synthesizer generates the lowest frequency, which is 143.00 MHz. If all the input pins are high (+8 volts), the synthesizer generates the highest frequency, which is 148.11 MHz. Consequently, the combination of the inputs produces frequencies within the 143.00 and 148.11 MHz range.

Figure 1 shows the schematic of the interface. The circuit uses all eight data output lines from the PC parallel port to program two 74LS373 D-type latches (U3 and U4) through two 4050 hex non-inverting buffers (U1 and U2).

The latches are the focal point of the interface. You program the latches to feed programming data into the transceiver. When the enable input (pin 11 of U3 or U4) is low,

data is loaded from the input pins. When the enable input is high, the data is "held" at the output. The latch is a perfect device for holding programming data and driving devices such as the synthesizer.

The STROBE output line from the printer port selects latch U3 and the INIT line selects latch U4. Only one 74LS373 latch can be programmed at a time. This arrangement allows you to latch 16 bits rather than eight bits. Remember, there are nine inputs to the synthesizer, and additional inputs for the simplex, +600 and -600 repeater offsets, plus the +5 kHz channel spacing input. That comes to a total of 13 inputs with three spares. I am using the spares to drive three LEDs for displaying status information for packet radio purposes.

There is an LED connected to each of the latch outputs. They let you see how your PC is programming your rig. You'll find them to be tremendous debugging aids if you want to write your own software for your rig.

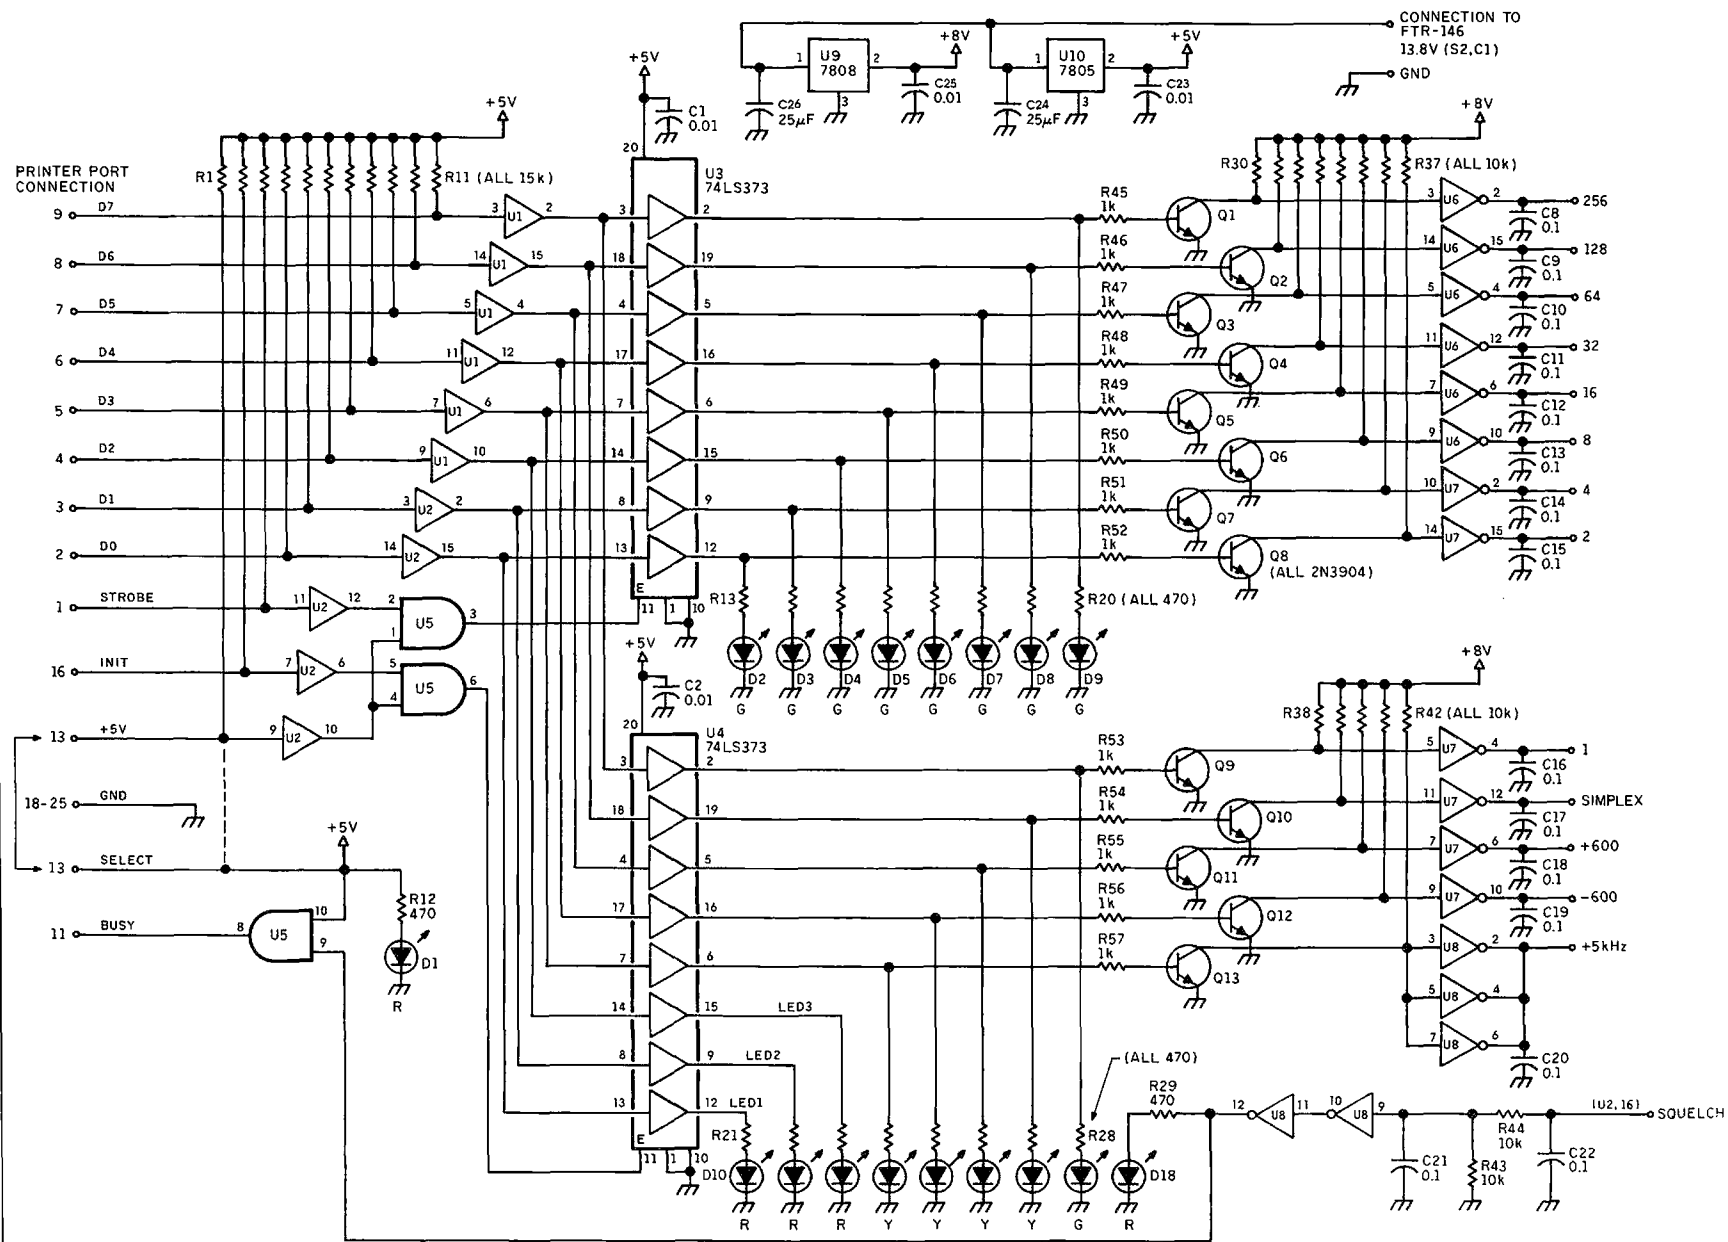

Figure 1. Schematic diagram of the FTR-146 transceiver-to-PC interface.

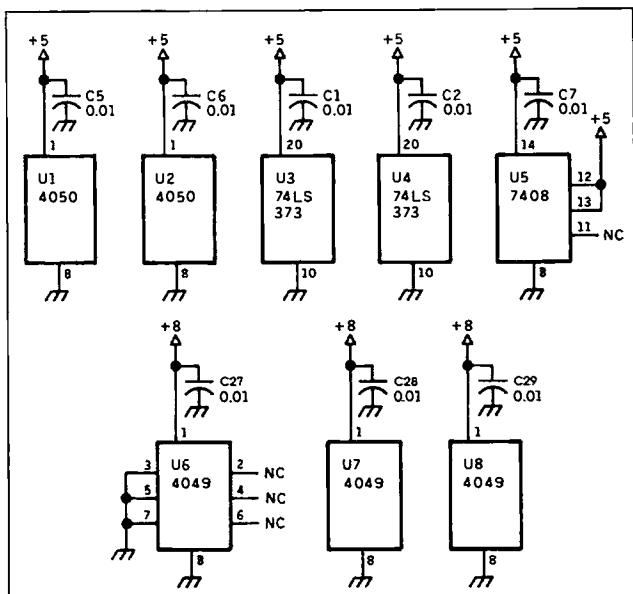

Figure 2. Power supply, voltage shunting capacitors and ordered gate connections for U1 through U8.

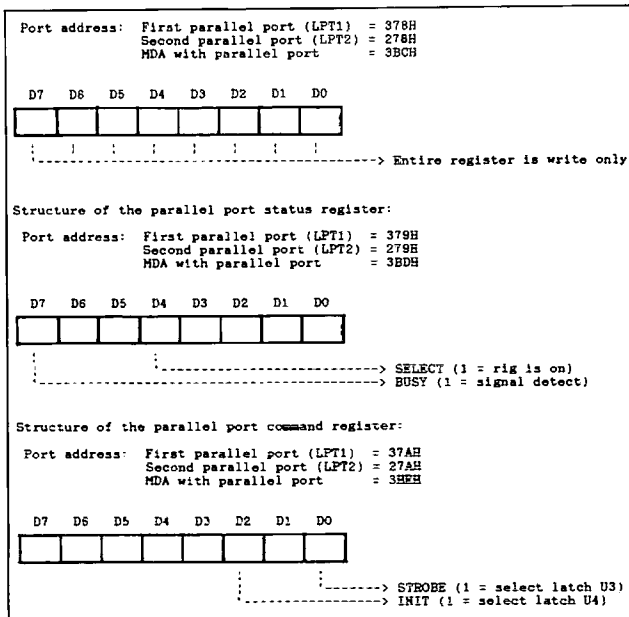

Figure 3. PC parallel port layout.

Thus far, we have dealt with TTL voltage levels (up to 5 volts) for the latches and the non-inverting buffers. The voltages coming out of the PC's parallel printer port pins are at TTL levels and are enough to drive the input buffers U1 and U2. Additionally, the voltages coming out of the latches, being slightly loaded down by the LEDs, are just high enough to drive other TTL devices, but may not be high enough to drive the synthesizer in the rig and definitely not enough to drive the repeater offsets and +5 kHz channel spacing.

I solved this problem by adding a voltage amplifier and a hex inverting buffer for each of the latch outputs (Q1-Q13, U6 through U8). If a latch output is low, it turns off a transistor, which causes the collector voltage to rise to the 8-volt supply voltage. This makes the associated hex inverter turn off (low) at the output, and therefore turns off an input to the synthesizer chip in the rig.

If a latch output is high, it saturates the transistor, causing current to flow. This drops the collector voltage below the operating threshold of the inverting buffer input, which causes its output to go high. This turns on an input to the synthesizer.

The above scenario is also the same for the repeater offsets and the +5 kHz channel spacing. However, I used three inverter gates (U8) to drive the +5 kHz channel spacing circuit. One gate is insufficient to source a full 8 volts for this input, due to the rig's circuit loading.

When you program the repeater offsets, you enable an oscillator circuit by applying a voltage (high) at the appropriate latch output. You are only supposed to select one. Be very careful as it is easy to enable or program two or three oscillators at the same time. You can control this by software and verify by observing the LEDs.

As mentioned in the introduction, another

feature of the interface is the signal detect input to the BUSY line of the printer port. The 3359 FM detector (U2, pin 16) in the transceiver has a squelch output pin that connects to a cutoff transistor (Q14 in the rig) for the audio amplifier. If there is a signal in the receiver portion, a voltage at the base of Q14 enables the audio amplifier, thus disabling the squelch. I connected pin 16 of U2 (in the rig) to the BUSY input line via the remaining inverting buffer gates (U8, pin 9 in Figure 1) to reduce the voltage to TTL levels. The buffer also lights an LED (D18) to indicate a signal is being received.

The SELECT input in your printer port is tied to the +5 volt supply. This merely serves as a signal to your computer indicating whether your rig is turned on, making your computer a little smarter.

The SELECT input is also tied to pin 9 of U2. I made this connection at the printer port connector. However, you may elect to wire the SELECT or +5 volts directly to pin 9 of U2 (dotted line on schematic and PC board). This voltage enables the other half of AND gates U5 for programming the latches.

Figure 1 shows the Vcc (power supply voltage) connection to U3 and U4 shunted with 0.01 µF capacitors. Figure 2 shows the Vcc connection to all the IC chips in the interface. Note carefully that U1 through U5 are connected to the +5-volt supply and U6 through U8 are connected to the +8-volt supply.

Figure 2 also shows the unused gates of U5 and U6. The unused inputs to U5 should be tied to +5 volts to minimize current and to prevent oscillation, while the unused inputs to U6 should be tied to ground to minimize current.

Construction

I planned to construct the circuit so that it would fit in a Radio Shack 270-274 metal

cabinet. I constructed the circuit on a Radio Shack 276-147 pre-drilled board and used 24-gauge bell wire for the point-to-point wiring. I used sockets for the chips so I could measure voltages later, before installing the chips.

[Ed. Note: A PC board is available for this project from FAR Circuits (see the Parts List for order information); also see Figure 4 for the foil pattern and parts placement.]

There was more than enough space on the board to mount all the parts of the circuit, except for the LEDs (I wanted them to be on the front panel). How you want to lay them out is pretty much up to you because parts placement is not critical. I carefully laid out the chip sockets on the board, making sure that there would be room for all the resistors and capacitors and point-to-point wiring (see Photo A). I soldered the sockets only at the opposite pins, just enough to keep them in place. This allowed me to insert the wires and leads directly into the socket pins and lightly solder them in place.

I carefully laid out how I wanted to line up the LEDs, with the programming LEDs on the top row and the offset and status LEDs on the bottom row (see Photo B). Since I like multiple colors, I used green LEDs for the top row and yellow and red for the bottom row. After drawing the LED layout and using it as a template, I drilled the holes and installed the LED caps. I also drilled the holes for the mounting hardware.

I cut another 276-147 pre-drilled board in half for use as an LED board. The half-size fits nicely inside the front panel. I loosely installed the LEDs on the LED board and mounted the board on the front panel. I used spacers for the 4-40 hardware to keep the board about 3/4" away from the inside cabinet surface. Then, I manipulated the LEDs (loosely hanging between the board and the

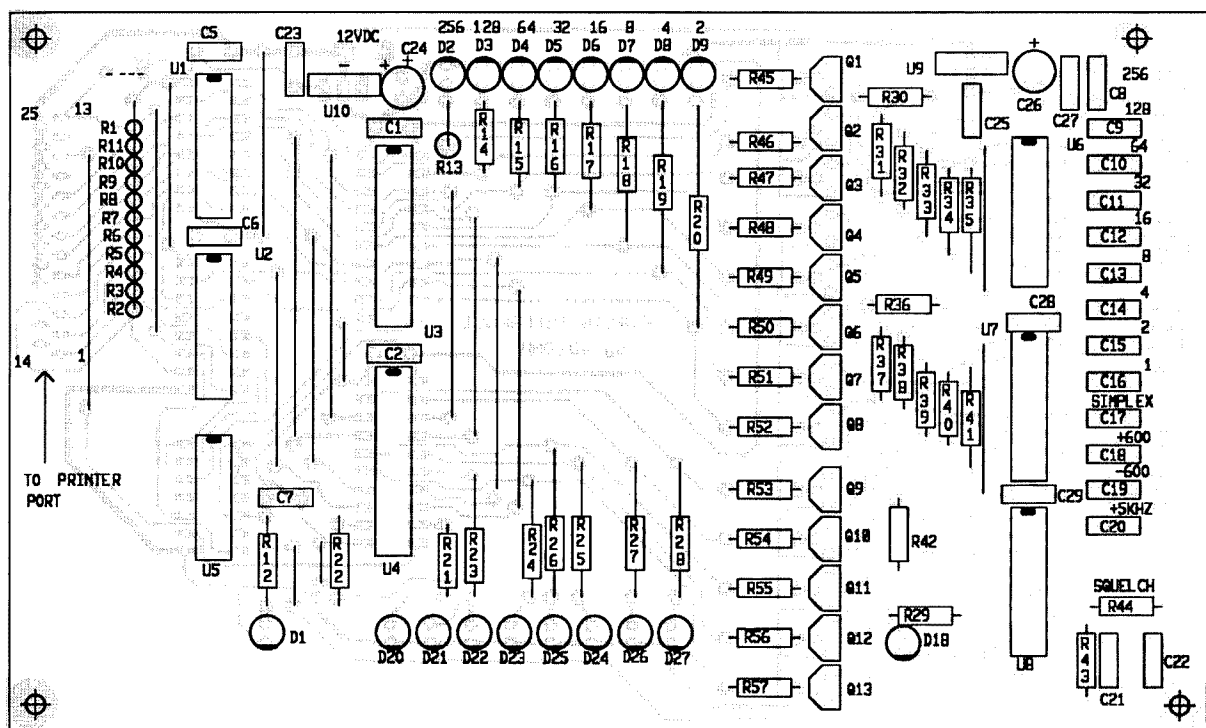

Figure 4.

inside cabinet surface) by grasping the LED leads and inserted the bulb parts into their respective caps. After making sure that the LEDs were firmly seated in the caps, I soldered the leads in place. This made it easier

to remove the board, install the resistors, and re-install the board. I used ribbon cables to connect the LED board to the main board.

I used a 25-wire flat ribbon cable to make the actual connections from the transceiver

to the interface cable (see Photo C). As a result, I was able to use the metal case and knob set for the rig from Ramsey because the ribbon cable fit snugly between the top and the rear panel. At the end of the ribbon

Photo B. The front panel of the FTR-146 interface. The PKT LED is connected to a modem interface circuit and is unrelated to this article. The switch on the right side of the panel is set at "AUTO," which allows latch (U4) to program the +5 kHz channel spacing. The other choices manually set the channel spacing to "off" or "on."

Photo C. Flat ribbon cable runs from the rear of the transceiver to the 25-pin male D-SUB cable.

cable is a male 25-pin D-SUB connector. I happened to have a length of 25-wire cable, so I attached a female D-SUB connector at one end and attached the other end to the interface.

Ramsey had the experimenter in mind when they drilled an extra set of holes in the circuit board for programming the frequency synthesizer. There are six sets of holes for building a diode matrix for six frequencies, and each are enabled by one of six positions

of the 12-position rotary switch S1 (the other six positions are not used). The seventh (and extra) set of holes is where I connected the ribbon cables. These holes have inputs for the nine input pins of the synthesizer (256 through 1), the transmit repeater offsets (simplex, +600 and -600), and the +5 kHz channel spacing. The right side of Figure 1 shows all the connections to the rig via the ribbon cable.

I attached a length of 25-wire cable to the computer side of the interface and attached a male D-SUB connector for the PC parallel

printer port. See the left side of Figure 1 for the wiring diagram. In reality, you can use a 15-wire cable instead.

To supply power to the interface, I connected the 13.8-volt power supply voltage from the off/on switch in the rig to the voltage regulators U9 and U10. Thus, the interface comes on only when the rig is on.

Check-Out

After thoroughly checking my wiring, I temporarily connected the interface to a 13.8-volt power supply through a 1-amp fuse. Fortunately for me, there was no

MULTIPLE REPEATER - LINK - REMOTE BASE CONTROLLER

Finally a controller that has solved control and audio interconnect problems between multiple radios. Your radio system can grow to multiple sites and stretch for hundreds of miles - and yet any radio can be fully controlled from any designated input.

The RBC-700 Repeater Controller is designed to support Repeater systems that require multiple radios connected together at a site. The RBC-700 utilizes a true 7 x 7 audio matrix switch which allows several conversations between ports at the same time. In the illustration above the 733 model is supporting a Repeater, 3 Duplexed Links to different sites, and 3 Remote Bases. Using simple commands, a user could tie the Repeater and a Remote Base to one Link, while the other Links are communicating through your site, holding separate conversations. Or, connect all of the ports together - like a big party line !!

Several models are available and are software configurable to support up to 3 Repeaters, 5 Duplexed Links, and 4 Remote Bases. A group or club can start with the basics and expand their controller anytime by simply adding boards and software. Free software upgrades for one year after delivery. Finally, a real controller for the Linked system operator !!

Multiple Independent Repeater control
Up to 5 Duplexed Links
Up to 4 different Remotes
Recorded Natural Speech Telemetry
Programmable Macros
Connect / Disconnect multiple Ports
Internal Receiver Squelch processing

Easy servicing
Integrated Autopatch
Expand at any time
Programmable Scheduler
+10v to +14v Supply
Standard 5.25" Rack Mount
Card-Cage design

smoke or short. After performing voltage checks, I installed the chips. I connected the interface to the computer parallel port and wrote a few BASIC programs to test it. I didn't have to test with the radio connected because I observed the results on the LEDs. After verifying proper operation, I ran the same tests while measuring the radio connections to make sure that the voltage outputs (from 6 to 8 volts) corresponded to the LED readouts.

Software

The printer parallel port contains three registers: the data register, the status register, and the command register (see Figure 3). The data and command registers are output registers and the status register is input. The base port address is hexadecimal 378 for LPT1, 278 for LPT2, or 3BC if you have a Monochrome Display Adapter. If you only

your port is configured as LPT1 (base port = hex 378).

The starting building block of any software you write is a GW-BASIC code fragment, shown in Listing 1. I chose the BASIC language for the sake of this article because everyone who owns an MS-DOS machine already has a BASIC interpreter.

Input to the code in Listing 1 is a 16-bit (2-byte) string (WORDS) containing the frequency inputs (9 bits), the repeater offsets (3 bits—only one can be 1!), the +5 kHz channel spacing (1 bit), and the three status LEDs (3 bits). This string corresponds to the outputs of the latches U3 and U4, consecutively.

To create the WORD\$ string, use lines 40000 through 40470 from Listing 3. This code fragment converts FREQ\$ (frequency and mode in ASCII) to WORD\$. The frequency is the actual frequency you want, such as 146.52 or 146.835. Mode must fol-

low the frequency after a comma and is a one-character transmit repeater offset character, which can be "S" (simplex), "+" (+600), or "-" (-600). If you don't specify a mode with no comma after the frequency, then simplex is assumed.

You can use this code to verify the integrity of the frequency/mode string FREQ\$. The program in Listing 3, which we will discuss later, asks for a frequency and uses the code fragment to verify and convert the input to WORD\$ and return a numeric status code, STAT%. IF STAT%=0, then FREQ\$ passed the verification edit and the code successfully converted FREQ\$ to WORD\$. If STAT%=1, then FREQ\$ contains a syntax error (no period in the frequency and invalid mode to name a couple of possible problems). If STAT%=2, then the frequency is outside the boundaries of the FTR146 transceiver.

The following two paragraphs describes the function of Listing 1 in detail: Line 42040 transfers the first 8 bits of

Our New COMMUNICATIONS DECODER Is A MUST For All Serious FM'ers!

Introductory
price: **\$199**

THE MODEL CD-1 DECODES & DISPLAYS:

- 104 DCS CODES (Digital)
- 50 CTCSS TONES (Analog)
- 16 DTMF DIGITS (Touchtone)

The CD-1 reveals everything you need to know to operate any open repeater or phone patch. Simply connect the CD-1 to your base, scanner or mobile radio.

When someone uses a system, the CD-1 decodes and displays the CTCSS or DCS code and in addition any DTMF codes that were used to control the system. (Including phone patch access codes and the phone number dialed). DTMF sequences are stored and automatically replayed just in case you missed something important. Use the CD-1 to learn police and fire codes too!

EXPERIMENTER'S HF DIGITAL COMMUNICATIONS SYSTEM (U.S. \$89+) (Fec, ASCII, Baudot, Amtor, Morse Packet, Pactor)

THE FABAMP CARD (Version FB10I for IBM compact, FB10A for Apple II)

A new low-cost experimenters plug-in card package, complete with assembly language source codes for the 7 favorite HF digital Tx/Rx modes for the IBM compatibles and Apple IIs.

UNIQUE DESIGN FEATURES...Built in i/o and modem. All software generated algorithms for syncing, sound/visual status for idles, control signals, iambic paddle inputs, split screen etc.

- Fabamp card [1_] \$89.00 (IBM Model FB10I) or [2_] \$99.00 (Apple II Model FB10A)
- 5" diskette software with shareware privileges for both tx and rx, at \$12.00 each mode.
 - Amtor (link up, eavesdrop)
 - Fec (100 bauds, WRU, error indications)
 - Selfec. Navtex (eavesdrop)
 - Baudot RTTY (45-300 Bd, Seical, WRU)
 - HF Packet (300 bds, monitor)
 - ASCII (50-300 bds, parity, encryption)
 - Morse (Autotracking rx, iambic key input, Farnsworth trainer, etc.)
 - New Pactor Starter toolkit (ASCII frame/control sig txrx)
 - Novel Experimenters "Equal Time-shared Synchronous Duplex mode" (E OSD)
- Add \$7.00 per software for beginners textbook/tutorial/source code, further experiments.
- or [] Special all of a, b, c above at \$159.00 + \$9.00 airmail worldwide delivery.

Further information welcome.

Photo D. FTRSCAN screen output on a color CGA monitor.

WORD\$ to the numeric variable FIRST. Line 42050 initializes a command variable (CMND) to set latch U3 in data input mode. Line 42060 sends the data to the latch through the printer port data register. Line 42070 sends a command through the command register to latch U3 to capture the data at its input (latch U4 is not yet selected and doesn't care what's in its input). Line 42080 sends another command to U3 to exit the input mode and "hold on" to the data at its output for pins 256 through two of the rig's synthesizer chips.

Line 42090 transfers the second 8 bits of WORD\$ to the numeric variable SECOND. Line 42100 initializes a command variable (CMND) to set latch U4 in data input mode. Line 42110 sends the data to the latch through the printer port data register. Line 42120 sends a command through the command register to latch U4 to capture the data at its input (latch U3 is not selected and is ignoring everything). Line 42130 sends another command to U4 to exit the input mode and "hold on" to the data at its output for pin 1 of the rig's synthesizer chip, the repeater offsets, the +5 kHz channel spacing, and the three status LEDs.

At all other times, the command register should contain 1 to keep the latches disabled (not loading data). The STROBE output in the printer port is inverted, so a 1 in the STROBE bit is really a low in the STROBE output pin.

When you first turn on your computer and radio, the LEDs will randomly light up. In my computer, every other LED lights up, and one or both latches may be in data input mode. I wrote a small BASIC program to initially program the interface during boot-up (Listing 2) from your AUTOEXEC.BAT file.

Using the Status Register

If you want to check if the radio is "on" using the status register, use the following sample statements (the ... represents your statements):

```
100 ISITON=(INP(PORT+1) AND 16)
110 IF ISITON=16 THEN ...: ' If radio is on.
120 IF ISITON=0 THEN ...: ' If radio is off.
```

```
100 SECOND=ASC(RIGHT$(WORDS,1)): ' SECOND = second 8-bit word
110 SECOND=SECOND OR 2: ' Turn on D2
120 MID$(WORDS,2,1)=CHR$(SECOND): ' Store change in WORD$
130 CMND=5: ' CMND = command to set U4 in receive
140 OUT PORT,SECOND: ' Write SECOND to data register
150 OUT PORT+2,CMND: ' Command U4 to receive data
160 OUT PORT+2,1: ' Command U4 to latch data
```

Listing 4.

If you want to check if the radio is receiving a signal through the status register, use the following sample statements:

```
100 RECEIVING=(INP(PORT+1) AND 128)
```

```
110 IF RECEIVING=128 THEN ...: ' If there is a signal.
```

```
120 IF RECEIVING=0 THEN ...: ' If there is no signal.
```

Programming the Status LEDs

The lower three bits of U4 control the lighting of the status LEDs. Basically, you only need to manipulate the lower 8 bits of the string WORD\$. You must maintain the first 5 bits if you want to keep the frequency and the offsets the same. The example in Listing 4 turns on status LED2.

You can use the logical operators available in BASIC to manipulate the lower three bits. The logical operators are:

```
OR to turn on an LED
AND to turn off an LED
XOR to toggle an LED
```

I encourage you to study your BASIC manual to learn more about them. They are quite easy to use once you get a handle on them. Here are some samples you can use in place of line 110 in Listing 4:

```
110 SECOND=SECOND OR 5: ' Turn on LED1 and LED3
```

```
110 SECOND=SECOND XOR 3: ' Toggle LED1 and LED2
```

```
110 SECOND=SECOND AND 248: ' Turn off LED1, LED2, and LED3
```

```
110 SECOND=SECOND AND 250: ' Turn off LED2 only
```

FTRSCAN

Listing 3 is a program called FTRSCAN. I am placing this in the public domain for your enjoyment, edification, and use. Basically, this program lets you enter a frequency, select a frequency from a list from file FTRSCAN.DAT, and scan the 2 meter band.

Initially, the program reads the FTRSCAN.DAT file (contains a list of your favorite frequencies) and lists the frequencies on the right side of the screen. The program then asks you to enter a starting frequency. After you enter a starting frequency, the program displays the frequency in the middle of the screen inside a box and lists the function keys in the bottom of the screen. Photo D shows a typical FTRSCAN display.

The following are the functions of the function keys:

F1 single steps the frequency down by 10 kHz.

F2 single steps the frequency up by 10 kHz.

F3 single steps the frequency down by 5 kHz.

F4 single steps the frequency up by 5 kHz.

F5 asks you to enter a frequency.

F6 sets the repeater offset to -600 kHz.

F7 sets the repeater offset to simplex.

F8 sets the repeater offset to +600 kHz.

F9 initiates scanning in reverse direction in 10 kHz steps.

F10 initiates scanning in forward direction in 10 kHz steps.

When you enter a frequency (function F5), enter it in this format:

freq,mode

where:

freq is the frequency (xxx.xx or xxx.xxx)

mode is the repeater offset:

= -600 kHz

S = simplex (default)

+ = +600 kHz

Examples: 146.43 147.06,+ 146.76,- 146.855,- 152.00,S

Each frequency listed on the right side of the screen corresponds to an alphabet. To select a frequency from the list, simply press a corresponding alphabet. For example, press B to select the second frequency from the list.

You can also move up and down the frequency list by pressing the up or down arrow key, respectively. The selected frequency is preceded by an arrow symbol shown on the screen.

You can use a word processor or text editor to create FTRSCAN.DAT, which is an ASCII file. Make sure that each frequency is followed by a carriage return and line feed. FTRSCAN will handle up to 24 frequencies, which is the maximum number of lines on the screen.

You can also listen in on a repeater input frequency by pressing CTRL-T (hold down the CTRL key and press the T key). The frequency box will show the input frequency. Press CTRL-T again to restore the repeater frequency. CTRL-T will have no effect on simplex frequencies.

To exit the program, press F5 and then press the RETURN key without entering a frequency. You can exit the program and still use the last selected frequency and be able to run other programs on your PC, just so long as you do not try to "print" anything to the parallel port. If you are capable of routing printer outputs through a serial port (by using DOS's MODE command) and have a printer that has a serial port, then you can print your files and still maintain the con-

nection of your interface to the parallel port.

The program in Listing 3 assumes you have LPT1 with a base port of 378 hexa-decimal. If you want to use LPT2 or a parallel printer port that is included in your monochrome video adapter, then change line 40 to reflect the port address. See Figure 3 for the possible port addresses.

Observations

It is very possible that stray RF will bounce around between the transceiver and your PC through the interface circuitry. All connections between the interface and the rig are shunted with 0.1 μ F capacitors. In my setup, I found about 10 frequencies that are unusable because of these stray signals. Fortunately, nine of them are on unused frequencies, leaving one that sits on a packet frequency. You can block these frequencies from your scanning by creating a frequency intercept table in your program, if you so desire.

The 5106 synthesizer is slow when locking onto a new frequency. This means that you won't be able to make your radio scan quickly like today's commercial scanners. However, you can successfully scan up to five frequencies per second. The actual scanning rate can be increased or decreased, depending on the squelch setting. I found that if I turn the squelch down very near the

Note: An etched and drilled PC board is available for \$9 + \$1.50 shipping per order from FAR Circuits, 18N640 Field Court, Dundee IL 60118.

Most parts are available from Radio Shack and JDR Microdevices.

threshold, the interface will scan faster. You can experiment with line 50 in Listing 3 to change the scanning rate. This rate works fine in my PC-XT running a 8088 CPU at 10 MHz, however you will need to significantly increase this value if you are using a much faster machine based on a 386 or a 486 processor.

Well, my dream of controlling a 2 meter rig using my PC is now a reality. One of my many projects is to develop a TSR (Terminate and Stay Resident) version of FTRSCAN so while working on another program I can use a hot-key to activate FTRSCAN, change a frequency, and return back to what I was doing. The list of software ideas is only limited by my imagination.

HAM HELP

Number 24 on your Feedback card

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS Special Events Message Area, #11. (2400 baud, 8 data bits, no parity, 1 stop bit.) Tel. (603) 924-9343. Please indicate if it is for publication. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

I want to contact Heathkit SB series owners/collectors interested in exchanging equipment, parts, manuals, or information. Contact Bob Schlegel N7BH, 2303 286th St. East, Roy WA 98580.

NEEDED: Manual/schematic, or a copy, for a KDK 2 meter mobile radio, Model #2033. Rick Labrecque

N1ITN, RR#1 Box 990, Dixfield ME 04224.

I am looking for a copy of the schematic diagram for a Conar Model 452 (two meter) transceiver. This radio was supplied as a kit for a National Radio Institute correspondence course in the late 70s. I will pay all costs. William Fritzsche K0SDZ, 1512 W. California Ave., St. Paul MN 55108.

Arnie Johnson N1BAC
43 Old Homestead Hwy.
N. Swanzey NH 03431

Notes from FN42

If you are anything like me (a dedicated ham), you like to receive things in the mail, such as: ham magazines, QSL cards with an SASE, letters from loved ones and friends, ham equipment catalogs, etc. I also enjoy receiving mail from other hams throughout the world, passing on important information about happenings in their area of a country or of the country itself. And what I enjoy even more is passing that information on to the thousands of readers of 73.

I have been blessed with many great Ambassadors through the three-plus years I have been putting this column together. Some have come, and some have gone. Some have become just too busy to keep it up and some just got tired (I guess). Some have become Silent Keys. Some have moved to other locations and haven't got settled in yet.

Some countries just haven't really gotten started with ham radio, either from the beginning or after changes in

political status, so there are no hams to pass the information on. Some countries are in such political and economic tangles that those in power or who have the money to be involved in amateur radio are too busy with other things to pass on ham information.

I used to think that being busy leaves no time to do other things, but I think I have proved this wrong. Some of the best college students I have seen in my teaching career have been very busy in campus activities and athletics. I have learned from them that they make plans and make every minute count. Being busy doesn't mean that there is no time for fun things; to the contrary—these students just plan properly to make everything happen.

What does this discussion have to do with ham radio? What I have been leading up to is that every one of us does have time to do many things, even if we think we are too busy. All it takes is a little planning. How long does it take to gather some ham news in one's area and write a half-page or page about it? How much time does it take it is done three or four times a year? I

don't think it takes THAT much time over a one-year period. Is that any excuse to not become a Ambassador for your country? NO! What if your English is not so good? Is that any reason not to become a Ambassador for your country? NO! I think I've done a good job so far in deciphering the reports from other countries.

So, as you can see from the previous arguments, there is no reason for you not to volunteer to become a Ambassador for your country. And the rewards: You get your name in print and get a free airmail subscription to your favorite amateur radio magazine, 73 Amateur Radio Today. And, last but certainly not least, the rest of the world gets to find out what is happening in your country. I think that is one of the most rewarding things about this job, besides working with the great people at 73. Even if you don't want to become a Ambassador, send me some information anyway.

Don't put it off; write me today, either at the magazine address or at the address at the beginning of this column. Send a small sample of your writing. Better yet, send me some information about what is happening ham-wise in your area. Do it today! Get involved in this great hobby of ours!

73 for now.—Arnie, N1BAC

Roundup

IARU Region 3 It has been an-

nounced that China has decided to allow individual amateur stations to operate after December 22, 1992. The call-sign prefixes will be BA, BD, and BG. The Chinese Radio Sports Association has been working on this for many years.

Philippines On behalf of the officers and members of the Benguet Amateur Radio Operators Network Society and the Texas Instruments Amateur Radio Club, we wish to express our profound gratitude for the publication of the information regarding the Special Event Station 4G2BAG commemorating the 83rd founding anniversary of Baguio City, Philippines.

As an additional note, we wish to inform all readers that Alvin 4F2AWE, one of the participating stations for the special event and the president of BARONS, Inc., became a Silent Key last 31 October 1992, at the young age of 24.

Russia/USA Downloaded from packet: The R&R Callsign Database containing 30,780 names and QSL addresses of stations in Russia and the independent republics is available for downloading free-of-charge from the Mountain Retreat BBS at (408) 335-4595. LLBS Sysops can FREQ the file R&RCALLS.exe. Anyone can download the file without upload restrictions or BBS registration. The program and data are shareware. The file is almost 1 megabyte long, so call in during cheap time.

The "A-Team" Outfoxes the Foxes
Almost all summer long serious intentional QRM plagued the main Tel Aviv 2 meter repeater. All but the strongest stations were at the mercy of some QRMers who seemed to be dedicated to systematically making life miserable for anyone wanting to use the machine. The lowlifes even QRM'd hams who, after being run off the R7 machine, went to other repeaters. Your faithful scribe was one of the unfortunate victims. On a few occasions the weekly Israel Amateur Radio Club net was disrupted.

There were some partisan attempts to nab the offenders, but alas, the interference persisted. Only once the trackers got organized and started to work as a team did they get successful. In this way, two offenders were tracked down and only then were legitimate contacts heard on the Tel Aviv R7 repeater.

On the weekly "Gal HaMeshudar," the IARC Newsmagazine on the Air, Tuvia 4X4GT, presiding as master of ceremonies, promised that soon the IARC would announce the name of the pirate whom the club's task force tracked down and caught. The IARC

has applied to the proper authorities and filed an official complaint.

The pirate, who interrupted communications on the Tel Aviv R7 repeater and on the other machines, was caught operating a high-power transmitter in a moving vehicle. Tuvia said that the offender will be sued for damages caused by his interference, including preventing the officials of the IARC to transmit information to the membership on a weekly net.

Now that the task force has been formed, Tuvia said, once they go into operation it is just a matter of minutes before they can track down the interfering station. He asked hams to install rotatable 2 meter beams to help pinpoint the location of jammers, and promised that the next issue of "HaGa" will feature a multi-element quad that is excellent for foxhunting.

As if to take up Tuvia's challenge, an unidentified station began to interfere with the transmissions on the net and, as in days gone by, the net turned into a shambles. In the next few days the jammer grew bolder, taunting the amateurs, and even dosing out some of the vilest language. The jammer claimed that he was "untouchable" and that they'd never get him.

The "A-Team" went into operation again and tracked him down to his place of work where he was doing his vile deeds. The details will have to go unchronicled for the time being, for this

is still a covert operation. The methods and identities of the live foxhunters must remain undisclosed as they must maintain their tactical advantage in keeping the repeaters clean. The bottom line says that teamwork is the only way to go when you have to out-fox the fox.

4X Delegation to AMSAT-UK
4X1AS, 4X1GP, 4X1RU, 4X4JI, and 4Z4RM were at the annual AMSAT-UK Colloquium at the University of Surrey in England. About 130 participants from around the world were present to hear and speak about developments in an amateur satellite program.

Shlomo 4X1AS announced that AMSAT-Israel shall become an affiliate organization of AMSAT-UK, drawing cheers from the participants.

Much was spoken about the Phase III-D satellite project. The bird in the works will weigh half a ton and will cost 3.8 million dollars, supported by donations from amateurs all over the world, as well as by a grant from the German government. The Spanish Amateur Radio Organization has pledged 10,000 Sterling to the project.

Many amateurs are benefiting from hamsats unknowingly. A lot of international packet radio forwarding is being done over a few of the "microsats," thus sidestepping the fickle and congested high frequencies. Thus, we would do well by offering our financial support to our nearest AMSAT organization, which

shares the responsibility for the building and launching of these satellites.

Above and Beyond the Call! The Huleh Valley hams let nothing get in their way when it comes to having full participation at their meetings. When it turned out that Eddie 4X6TE of Kibbutz Kfar HaNasi had guard duty the night of their scheduled get-together, the hams moved tables, chairs, food, and drink into the guard house and held their meeting there.

National Field Day A national Field Day was held on September 19th. In the north, a station was set up in the Carmel Forests; in the center at the Silent Key's Forest at Ben Shemen; and in the south at the Yatir Forest north of Heer Sheva. Besides the operation on the HF and VHF bands, there were the traditional burnt offerings of steaks and shish kebabs.

Holy Land DX Contest 1992 Results The IARC Contest Manager, Shalom Beitcher 4Z4UT, has tabulated all the results of the past Holy Land DX Contest, which was held on April 18th, 1992. Participants from 27 countries on four continents sent in 247 logs which have been checked and the winners are hereby declared in order (1-2-3): Worldwide Hams—LY2WW, UA6JD, LY3BP; SWLs—LYR1751, ONL383, SP9-4006-KA; Israel—4Z4DX, 4X4KK, 4X4JU. A booklet of the complete re-

Wayne is mad as hell ...
...and he doesn't want you
to take it anymore!

Declare War!

On Our Lousy Government

Fed up with the mess in Washington?
The mess in your state capital?
Poverty, crime, our failing schools?
Wayne Green has solutions.
Clever solutions.

Wayne Green's unique reasoning is intriguing — even delightful. Whether you are horrified by his proposals or you embrace them, it is impossible to ignore the basic lesson he presents: It is time to bring logic — not emotions — to bear on America's dilemmas. His spin on America in the 90's helps us to understand how simple the seemingly complex issues are. All it takes is looking at them from an entirely new viewpoint.

Now available in one complete volume, *Declare War!* is full of thought provoking ideas and solutions to some of the most difficult problems facing our country today.

PEOPLES REPUBLIC OF CHINA

Rick Hunter, Chief Op. BY1QH
Room 316, Building 25
Tsinghua University
Beijing 100084

Peoples Republic of China

Four of the main members of the Tsinghua University Amateur Radio Club (TUARC), Rick, Hao, Jaro, and Mes, went to BY1PK for a friendly visit November 20.

We were warmly received by Mr. Tong Xiaoyong, the president of this Number 1 station in China. We were deeply impressed by their ICOM IC-781, 2 meter repeater, SSTV rigs, and much more. We learned quite a bit about the latest developments of ham radio in China and throughout the world. Mr. Tong kindly presented us with some amateur radio related computer programs and PBBS documents. Many of these programs were written by Mr. Yan, another senior op at BY1PK.

Our ham radio class that started December 1st is going very well. Jean, Violet, Nick, and Gray (not Gary, hi!) have been taught the basics of amateur radio and the international phonetic alphabet by Rick. The four students will be practicing real-time operations on SSB shortly and are looking for voice partners to help. Please listen for them on BY1QH.

We are now receiving responses from around the world, thanks to packet and 73. Several of the latest

are Immo DK6CC and Johann ZS3AAK. We are very happy to hear that Immo is interested in learning languages also.

We have surprisingly found that the RTTY propagation is no less than perfect between the USA and Beijing at about 0000 UTC. Although we can't promise a strict schedule, we will attempt contacts on 20 meters whenever available. Don't forget to check your local DX packet cluster for spots.

BY4AA, founded on October 12, 1983, is one of the most famous stations in China and is the ARS of Shanghai Radio Sports Association, located in the biggest city in BY-land. BY4AA runs CW, SSB, SSTV, packet, and a 2 meter repeater. Many member hams participate regularly in CQWW and WPX contests. Every New Year's Day, a Shanghai-Yokohama sister-city link is established with JH1ZCT. The current president is Mr. Xu Ru and the chief op is Mr. Hu Songqing. For further information, contact BY4AA, PO Box 085-205, Shanghai.

BY1QH is currently registered at the following three BBSs: JA5TX.JPN.AS; BV5AG.#APL.TWN.CHN.AS; VE7CIZ.#VANC.BC.CAN.NA. TUARC has almost daily access to all of them. Those who can not contact these BBSs directly can pass messages through DK0MHZ and ZSSS in Europe and Africa, which will then pass those messages onward.

And lastly for this month, our thanks to Wen-Long BV3AC for his kind offer of help in our search for the 2SC2652 transistor we need; to George VE7CIZ and Werner, the Sysop of DK0MHZ, for their great jobs; to Amie N1BAC for his frequent concern about TUARC; and to Joe ZSSS for his kind offer to put our newsletter into the ZS packet network. Finally, thanks to Mitsuo JA5TX and Katy BV5AG, without whom nothing could be achieved.

Comments and news are certainly welcome. Moreover, please don't hesitate to ask if TUARC can be of any help to you. Remember, you have quite a few friends in Beijing. 73 from Rick and the TUARC.

Why buy a TNC?

PC HF FAX + PC SWL \$179.00

SPECIAL COMBINATION OFFER

For a limited time, if you order PC HF FAX \$99 (see our other ad in this issue), you can add our new and improved PC SWL 3.0 for \$80.00 instead of our regular low price of \$99.00.

PC SWL contains the hardware, software instructions and frequency lists needed to allow you to receive a vast variety of digital broadcasts transmitted over Shortwave radio. At your need, a any IBM PC or compatible computer and an SSB shortwave receiver. The product consists of:

- Demodulator
 - Digital Signal Processing Software
 - 200 Page Tutorial Reference Manual
 - World wide Utility Frequency List
 - Tutorial Audio Cassette with Samples
- PC SWL automatically decodes Morse code, RTTY, AMTOR, STOR, NAVTEX and ASCII.

PC SWL lets you tune in on world press services, meteorological broadcasts, ham radio operators, coastal shore stations, aviation telex and much more digital action on the shortwave bands. Why pay for another expensive box when a simple interface and your PC can do the job?

ADVANCED FEATURES:

- Tuning Oscilloscope
- Digital Waveform Presentations
- Auto Calibration and Code Recognition
- Continuously Tunable Filter Frequencies
- Variable Shift
- Adjustable CW Filter Sensitivity
- Unattended Capture and Printing
- Integrated Text Editor
- Integrated Log and Database
- Shift to DOS applications
- Seamless Integration with PC HF Facsimile

Call or write for our complete catalog of products. Visa & MasterCard welcome.

Where in the World Are We?

Many students are, to put it mildly, ambivalent about schoolwork. They labor over language arts, muddle through math, and sigh over social studies. In teachers' rooms all across the country the conversations always get around to the topic of how to improve motivation in different lessons. It's perhaps the greatest challenge of the decade to inspire and stimulate youngsters while instructing them in the basics.

Fortunately, the teacher or instructor who uses amateur radio in the classroom has a head start on highly motivational lessons. The traditional, "Now open your books to page 456 and read about Germany" no longer can compete with the "live action" lessons a radio teacher can provide.

Aside from making contacts with citizens from different regions of the world, children can participate in many wonderful follow-up activities which can add fun and excitement to their lessons. We all know that learning is more effective

when it is relevant and challenging to the student.

I'm in the enviable position of being able to teach across the curriculum lines in my 6th-, 7th-, and 8th-grade ham radio classes at Intermediate School 72 in Staten Island, New York. The most obvious correlation of curriculum, however, either before or after a radio contact, is with geography skills. I'll share some of the best and most effective geography activities I've used with my youngsters through the years. The basic premise of each lesson can be modified to fit the needs and abilities of different age groups.

Pumpkin Globes

First, I refer you to my column "What Next?" in the February 1992 issue of *Radio Fun* magazine. In it I share a really funtastic lesson where I have the kids bring in pumpkins and water-soluble markers. (This is a great project to do in the fall, right around Halloween). I divide the class into groups. Each group is provided with a globe which will be the model for their "pumpkin globes." This follows a discussion about the differences between a wall map and a globe. Surprisingly, few children could articulate the different purposes of each. For example, the globe shows only half the world at

Tom KB2NJZ points to a spot on the wall map where the class just made a contact

AMATEUR TELEVISION

TVC-4G

SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. Others may be retransmitting weather radar during significant storms. If it is being done in your area on 70 CM - check page 413 in the 91-92 ARRL Repeater Directory or call us, ATV repeaters are springing up all over - all you need is one of the TVC-4G ATV 420-450 MHz downconverters, add any TV set to ch 2, 3 or 4 and a 70 CM antenna. We also have downconverters and antennas for the 900 and 1200 MHz amateur bands. In fact we are your one stop for all your ATV needs and info. Hams, call for our complete ATV catalog - antennas, transceivers, amplifiers. We ship most items within 24 hours after you call.

one time, but it is more accurate in distance, direction, size and shape.

The children use the markers to produce a pumpkin that has North and South Poles, the equator, the prime meridian, the seven continents, and the four major oceans. Everything gets labeled, including their own location. It's advisable to initiate this project rapidly, because the pumpkins have a tendency to spoil quickly in a warm classroom.

The World Carpet

Several years ago I picked up a World Carpet at a local flea market. I spread it on the floor and let a group of students enjoy the "world at their feet." The floor map is a fun way for the kids to locate different areas that we're studying about. Each class gets to make up its own game to play on it. We now have quite a repertoire of games that have been created.

DX Activities

Sometimes when propagation is really good for us on the CQ All Schools net I let the children select their favorite DX contact of the month. I then have them plan a trip to that country or part of the world. They utilize language arts skills by writing letters to their radio contacts for more information, and to embassies and tourist bureaus for brochures. Youngsters are taught library and research skills to help them locate addresses. They must present an oral report describing the route they will take to get to

their destination, the budget (an itemized account of expenses), and a scrapbook which highlights the points of interest to visit in that area.

I often work with the social studies teachers to better coordinate a stimulating introductory lesson or to follow up a geography lesson in a meaningful way. Current events takes on a whole different level of relevance when the radio can bring worldwide events into the classroom. After a radio contact with a school that had just experienced an earthquake tremor in Southern California, my classes brought in over 50 projects of every type and description that portrayed interesting facts about earthquakes.

The kids especially enjoy speaking with other young people their own age. They are always surprised to learn how much they have in common, like not liking school cafeteria food, and worrying about grades. They delight in uncovering their differences and eagerly look forward to receiving letters and pictures from children far away.

Make It Interesting and Relevant

Geography is an important part of a school's curricula and, like everything else you do in the classroom with the radio, it should be presented in a creative and meaningful way.

There are always interesting events going on all across the country that are designed to stimulate school children's awareness of geography. The following list may provide you with just the thing

you're looking for to add some "zip" to your lessons. Please write to me and let me know if you have success with any of these activities and tell me how you used it in your classroom.

Nystrom is offering a *free map of the Commonwealth of Independent States*. Contact the Nystrom Map Co. (3333 Elston Ave., Chicago IL 60618-9949) to request a copy of the map. Quantities are limited.

American Express is sponsoring the *American Express Geography Competition*. It offers over \$100,000 in prize money. This year students in grades 6 through 12 are eligible to participate in this exciting, challenging program. Call 1-800-395-GLOBE, Monday through Friday 10 a.m. to 7 p.m. Eastern time, for details or to obtain entry materials for the competition.

From October 6, 1992, to March 7, 1993, The Cooper-Hewitt National Museum of Design at 2 East 91st Street, New York City, will host an exhibition of more than 400 historic and contemporary maps dating from 1500 B.C. to the present. *"The Power of Maps"* examines the significance of maps as instruments of communication, persuasion, and control. It will be accompanied by lectures, seminars, workshops, and tours, as well as programs designed for schools, teachers and families. For more information, call Deborah Perlberg at (212) 860-6868.

World Map-A-Thon is a two-week program you can run anytime from Oc-

tober through April. It is sponsored by Save The Children, a private, non-profit, non-sectarian organization which has served impoverished children and their families since 1932. During the first week, students study the nations of the world and ask relatives and friends to pledge donations based on how many countries they will be able to identify. During the second week, students get to see what they've learned, collect their pledges, and receive their own world maps to take home. For more information, contact Linnah Madumaju, World Map-A-Thon, Save The Children, P.O. Box 990 Westport CT 06881-0990; 1-800-243-5075.

"See Me, Share My World: Understanding the Third World Through Children's Art" is a global education project of PLAN International, USA. It is a supplementary teaching unit designed for upper elementary grades. The unit is based on children's art from six developing countries that can be integrated into geography programs. Contact Meg Warren at 1-800-556-7918.

Why not make a New Year's resolution to try at least one new idea in your geography lessons?

Youth Forums

If you know of any articulate and enthusiastic young hams interested in appearing at national youth forums, have them contact me at P.O. Box 131646, Staten Island, NY 10314-0006 (718) 983-1416.

Link Communications RLC-1 Repeater and Linking Controller

- (2) Full Featured, Full Duplex, Repeater/Link Ports
- Both ports can operate as Connected or Stand Alone Repeaters, Cross-Connected Link Ports, or Both
- Each Port has its own ID message, Courtesy Beep, Hang Timer, TOT Timer, ID Timer, and CW Frequency; All user Programmable
- Completely DTMF Programmable, No Factory ROM programming needed
- (4) Analog Lines Programmable for Temperature and Voltage Readings
- (4) Input Lines for Contact Closure Readings at your repeater site
- (5) Output Lines for control of external peripherals, and site functions
- Both ports have COR and PL inputs allowing off site access changes
- DTMF access from either port, with EPROM Variable Storage
- 2400 Baud Serial Port allows Computer, Packet and Modem programming
- All commands can be renamed from 1 to 4 digits in length
- Independent DTMF muting function can be assigned to each port
- Analog Lines have Voltage source for the LM335 Temperature Sensor
- Doug Hall RBI-1 Remote Base Control of Kenwood Radio Support
- COR polarity jumper, and -6dB/Octave de-emphasis jumper per port
- DTMF valid LED allows visual indication of valid received tone
- Each port has its own DB-9 connector for radio port connection
- Small board outline, only 4.50" x 7.50" : Low Power, only 25mA Current Draw
- Each Link port can be expandable up to 3 links using the RLC-6 Link Expansion
- Optional 19" Rack Mount Cabinet for mounting the RLC-1, the RLC-6 Boards

Number 27 on your Feedback card

Compiled by Hope Currier

STARTEK INTERNATIONAL

The new model ATH-15 from Startek International is a frequency counter/frequency finder with an instant-reading RF signal-strength bar graph in a pocket-size aluminum cabinet. The fast response time and ATH™ (automatic trigger and hold) feature on this unit offer a distinctly new and improved feel to the operation of a portable frequency counter. The ATH-15 can read frequencies from 1 MHz to 1500 MHz, and the 10-segment 2"-long LED bar graph can give an instant RF signal-strength indication from signals below 1 MHz to over 4 GHz. There are two ranges with three selectable gate times on each range; maximum resolution is 10 Hz. The new ATH feature eliminates random counting

and false readings. The response time from the beginning of the input signal to a stable accurate display has been dramatically reduced.

The ATH-15 comes with factory-installed NiCd batteries. It is housed in a rugged, attractive black anodized aluminum cabinet measuring 3.5" x 4" x 1", and weighing about nine ounces. The ATH-15 is \$235, the CC-90 case is \$12 and the TA-90 antenna is \$12. For more information, contact *Startek International, Inc.*, 398 N.E. 38th St., Ft. Lauderdale FL 33334; (305) 561-2211, (800) 638-8050, Fax: (305) 561-9133. Or circle Reader Service No. 202.

AMATEUR RADIO ENGINEERING

Amateur Radio Engineering has introduced HamLink™, a telephone interface that goes between a telephone line and the computer port of your transceiver or receiver, allowing complete control of your radio. HamLink can control the frequency of a radio, mode, or band; scan memories; and operate in split mode. HamLink is even able to share a

telephone line with a family answering set without problems. You can control your transceiver from a Touch-Tone phone anywhere in the world. You can monitor DX frequencies and work the rare ones from

your office. If you live in a condo and can't have an HF station, you can put HamLink at a friend's home or a club station and use it by telephone.

HamLink is priced at \$269 and comes with a one-year limited warranty. For more information, contact *Amateur Radio Engineering, Inc.*, P.O. Box 169, Redmond WA 98073; (206) 882-2837, Fax: (206) 861-5780. Or circle Reader Service No. 201.

HART PUBLISHING

Hart Publishing has released the 1993 *Amateur Radio Mail Order Catalog and Resource Directory*. This is the fifth edition of this catalog and it has 250+ pages, nearly 200 categories, and more than 1,600 entries of mail-order products and services for hams. The catalog is categorized and alphabetized into easy-to-find headings from "Alternative Energy" to "Weather Instruments." Listings include the name, address, phone and fax number of the vendor, plus a description of products or services. And this year

the catalog includes "A Library of Tips" from Bill Welsh W6DDB, columnist and author, who has for many years provided the radio newcomer with easy explanations of the jargon and theories of the hobby.

The single issue price is \$14.95, plus \$3 postage via priority mail. For more information, contact *Hart Publishing*, 767 South Xenon Court, Suite 117, Lakewood CO 80228; (303) 987-9442. Or circle Reader Service No. 206.

DWM ENTERPRISES

The "Pill Bottle Antenna Tuner" from DWM ENTERPRISES is equipped with just two rugged parts: the tuner's inductor, made from a pill bottle; and durable #22 wire wound and tapped at various intervals along the coil to cover the 80 through 10 meter bands. An alligator clip is used to tap the individual bands.

Tuning for SWR is accomplished with a high quality Jackson Brothers 365 pF variable capacitor. The inductor and variable capacitor are mounted on cedar wood stock, giving the tuner a beautiful old fashioned look. Fahnestock clips are used for input and output connections. A variety of antenna designs can be used with this tuner, and experimentation is encouraged. It has been tested to over 150 watts output without arcs or sparks. It is great for both QRP and QRO, for portable or shack operation, for new rigs or old.

The "Pill Bottle Antenna Tuner" is priced at \$27, plus \$3 S & H, and comes completely assembled and bench tested. For more information, contact DWM ENTERPRISES, 1709 N. West Avenue, Suite 103, Jackson MI 49202; (517) 563-2784. Or circle Reader Service No. 203.

TRIPP LITE

The BC 400 from Tripp Lite is the smallest, lightest 400 VA battery back-up (UPS) system anywhere. This new unit combines outstanding performance from its redesigned circuitry for powering desktops PCs, phone systems, cash registers or internet hardware such as hubs, bridges and routers. The UL-listed BC 400 features two spike-protected AC outlets, large batteries for longer battery life and a highly efficient pulse-width modulated waveform output.

The BC 40 carries Tripp Lite's Ultimate® Lifetime

Insurance, which provides for the repair or replacement of connected equipment up to \$25,000 if damaged by a surge, including direct lightning strikes. The suggested retail price is \$219. For more information, contact Tripp Lite, 500 N. Orleans, Chicago IL 60610-4188; (312) 329-1777, Fax: (312) 644-6505. Or circle Reader Service No. 204.

MING COMMUNICATIONS

The AUTO-ID automatic message broadcaster from Ming Communications is a solid-state digital voice recorder developed specially for two-way radios. It simply plugs in between the radio and its microphone. With the use of your radio microphone you can record up to five separate messages that can be played on the air by pressing one of the five message buttons. The AUTO-ID also has a built-in timer that

monitors your PTT activity. Record your station identification and thereafter any time you are on the air the AUTO-ID will broadcast your message ID for you. The ID's timer can be set for intervals of three or nine minutes, or it may be set to broadcast your message every time you use PTT. With the use of the AUTO-ID's built-in speaker you can monitor the message that the AUTO-ID is broadcasting, regardless of whether the selected mes-

sage was broadcast automatically or manually.

The AUTO-ID comes with plugs for an Alinco or Kenwood mobile amateur radio. There are accessories available to interface the AUTO-ID to most other types of radios. The price is \$149.95. For more information, contact Ming Communications, 2948-1/2 Honolulu Ave., La Crescenta CA 91214; (818) 249-3006, Fax: (818) 248-0840. Or circle Reader Service No. 205.

Consumer Complaints

We get a few letters every week from hams who are having a problem, real or imagined, with one of our advertisers. Every once in awhile we are alerted to a real scam, and we quickly take appropriate action. Most of the time, though, the problem ends up being either a misunderstanding by the customer, an honest and correctable error on the part of the business, or some factor beyond the control of either that has been blown out of all proportion by one or both parties.

Even though there is little we can do about most complaints other than pass them along to the company involved (with a staff of less than 10 people, we really can't act as consumer watchdogs for the amateur industry), we are glad that our readers inform us of when they're having problems. Every once in awhile, especially if one of us here at 73 happens to be friends with someone at the "offending" company, we'll make a phone call or two to see if we can get things straightened out.

The other day I received a six-page, photocopied newsletter that was dedicated to complaining about a longtime 73 advertiser. It appears that this guy got ticked off at the company, and then sought out and found a bunch of other people who had complaints about this company, and he put them all together in this newsletter-type arrangement and mailed it out to a bunch of hams (or maybe he just mailed it to us). The thing that is unusual about this instance is that I happen to be friends with the president of the company in question and have always found him to be one of the nicest guys in the amateur radio industry. I have used his products and have never had a problem with them. In fact, my experience has been that this particular company is one of the best when it comes to helping customers who have problems or questions.

Just last week, we got a call from a reader who was having a problem getting something shipped from a mail order company. He said his check had been cashed, but he had not received his product yet, and it had been "almost four weeks." I asked the gentleman whether or not he had written to the company, inquiring about the status of his order. He said he had called, but was connected with an answering machine (with many small mail order companies being operated part-time from people's homes, this is not that unusual). I quickly looked up the ad in a recent issue, and right there in easy-to-read type was "please allow 4-6 weeks for delivery." I pointed this out to the gentleman, who didn't seem to feel that the company should cash his check before he received his product. I tried to explain how that happens, but this guy wasn't interested. By now I knew that this ham was more concerned with blatching than he was in receiving his product. I advised him to put everything in writing and send it to the company. If he didn't hear anything in two weeks, I invited him to call me again.

While it is important that you share with us any problems you're having with our advertisers, we would all be better off if you made sure you actually have a problem before asking us to look into it, or before unjustifiably slandering the name of a good company.

If you think you have a complaint, the first thing to remember is to leave a paper trail. That means all of your contact with the company should be in written form, and you must keep copies of everything. When you speak with someone on the phone, get their name and make a note of it, as well as the time and date of the phone call and what was discussed. If something important was implied or promised during the phone con-

versation, follow up the call with a letter reiterating the main points of the understanding.

Make sure you give the company sufficient time to process your order. Unless you have paid extra for next day delivery, most companies use regular package delivery or parcel post. That can take weeks to cross the country, so don't compare the speed of the company in the next town with one halfway across the globe.

If a reasonable length of time has passed (four to six weeks is pretty standard) and you still have not received your item, make a phone call and follow it up with a letter. If you have a canceled check or credit card bill that lists the company's charge, make sure you include photocopies of them. You will usually find that any delay in shipping your product to you is caused by: a) the product was shipped, but has obviously been lost in transit, or b) some part or item is on back order from the company's supplier.

A company should not charge your credit card unless they have processed the order. If your order has been shipped, the company can put a tracer on it. This might take a day or two, but it's not the company's fault. Checks are deposited on a daily or weekly basis, so it is possible that you could have received the canceled check before receiving your item. Either way, you have the right to cancel your order and receive a full refund if you haven't received the item within six weeks. You don't have to be nasty about it. Simply inform the company in writing that you are canceling your order.

If you already have the product and are not pleased with it, first make sure that it is installed correctly and that you fully understand how to operate it. A friendly call to the company will usually get you all the help you need in figuring out how to install or operate some of the complex pieces of gear we use these days.

If you truly feel that something is not right with the item, it's worth a telephone call to the company before shipping the product back to them. Remember, the company wants you to be happy with the product. That's how they stay in business. They aren't out to screw you, but if you start screaming at someone on the phone about their "piece of crap that doesn't work" you probably won't make any friends. Explain the problem you're having, and give them a chance to fix it. Don't expect the person who answers the phone to know what you're talking about. Also, don't be surprised if you get transferred around a few times or if someone offers to take a message and have your call returned later. Remember, they're trying to help you, and they are fully aware that it is in their own best interest to solve your problem.

If you have to return the item for repair or replacement, include a brief note outlining the trouble you're having and attach it to the piece of gear. Also, include a letter (keep a photocopy) outlining what you were told on the phone and asking for what you want ("Please repair and return to me . . ." or "Please return my purchase price . . .").

Only after you have exhausted all other avenues should you bother to contact the magazines. We usually can't do much except note your complaint. If we start getting a lot of complaints about the same advertiser we will look into it, but a single dissatisfied customer does not mean the company is run by a bunch of crooks.

It has been my experience that, with very few exceptions, the amateur radio industry is serviced by some of the nicest people and most honest companies anywhere. As long as we all treat each other with a little respect, I'm sure that your problems will be solved. Usually all it takes is a little communication. Isn't that what this hobby is all about?

PROPAGATION

Number 30 on your Feedback card

Jim Gray W1XU

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

Traditionally, March can be a very good month for radio propagation on the HF bands. The spring equinox on March 21 brings 12 hours of darkness and daylight, and the ionosphere has good UV excitation once again. March is also a month of wind and storms so you can look forward to some days of excellent HF conditions and good weather, as well as some days of very poor propagation and weather. The daily chart shows the poorest propagation conditions during the week of March 7th to 14th. "Good" propagation is expected between the 22nd and 28th, while only "Fair" propagation is anticipated for the rest of the month, when conditions may be very unsettled and the ionosphere variable from day to day. Be aware of the possibility of some extreme weather on the days surrounding the 8th and the 12th. Propagation can be very good or very poor immediately following a solar flare or some other major disturbance on the sun. Usually a "blackout" is followed by a day or two of very good conditions on the HF bands. March 30th and a day either way could be "Very Poor."

Unexpected Benefits

You may have noticed that December 1992, ordinarily expected to exhibit poor DX conditions, was unusually active and a "Good" month for DX, due to the solar flux rising to values between 140 and 160, and magnetic field indices lower than usual with a quiet field. These are the conditions that prevail as this column is being prepared and—frankly—somewhat of a surprise to this author.

On "Good" (G) days, you may expect fairly good openings on north-south paths for the 10-12 meter bands, in the afternoon, and also excellent skip to Africa and the Pacific. Openings to Europe will be fewer, but good short skip from 1300 to 2300 miles during daylight hours should occur. The 15 and 17 meter bands should provide good worldwide propagation on "Good" days during the daylight hours, and excellent trans-equatorial conditions, peaking during the afternoon hours.

The 20 meter band ought to be very good from sunrise to sunset, with conditions peaking during the early morning and mid-afternoon hours. The 30 and 40 meter bands will show fine DX opportunities during the late afternoon and through the evening hours, and again in the early

morning hours. Short skip between 100 and 1,000 miles during the day, and beyond 1,000 miles at night, should prevail on "Good" days. The 80 and 160 meter bands should show fairly good DX after sunset, with 160 peaking at midnight and again just before sunrise. DX on 80 meters should be good at these times, and short skip up to 1,500 miles or so should be good during nighttime hours . . . again on the "Good" days. "Fair" (F) and "Poor" (P) or "Very Poor" (VP) days will seem almost impossible . . . with the lower HF bands affected least and the higher HF bands affected the most. Even on "Poor" or "Very Poor" days, an occasional opening may occur on north-south paths across the equator. Enjoy March; it ought to be interesting.

73 Amateur Radio Today

April 1993
Issue #391

TABLE OF CONTENTS

FEATURES

- 10 Mini-Quad Loops**
Three-fifths-size loops with full-size performance.NH6XK
- 12 Copper Dual-Band Super J-Pole Antenna**
Build it in less than an hour.KA0NAN
- 17 HR2510 Hi-Power Modification**
Increase the performance of this popular HF rig.Merrill
- 18 10 Meter X-Beam**
Upgrade your antenna as well as your license.N5SJZ
- 26 Lightweight, Collapsible Quad for 2 Meters**
Excellent performance in a small package.AA1EX
- 30 Want a Dish?**
Building your own is easier than you think.WA8WBP

REVIEWS

- 24 The Ultratorch**
A tool for liberation.N4RVE
- 36 The jCom Zetel SDP-600 Smart Patch**
A topatch at a reasonable price.WB9RRT

Build your own satellite dish . . . see page 30.

DEPARTMENTS

- 78 Above and Beyond
- 81 Ad Index
- 64 Ask Kaboom

Manuscripts. Contributions in the form of manuscripts with drawings and/or photographs are welcome and will be considered for possible publication. We can assume no responsibility for loss or damage to any material. Please enclose a stamped, self-addressed envelope with each submission. Payment for the use of any unsolicited material will be made upon publication. A premium will be paid for accepted articles that have been submitted electronically (CompuServe ppn 70310.775 or MCI Mail "WGEPUB" or GENie address "MAG73") or on disk as an IBM-compatible ASCII file. You can also contact us at the 73 BBS at (603) 924-9343, 300 or 1200 baud, 8 data bits, no parity, one stop bit. All contributions should be directed to the 73 editorial offices. "How to Write for 73" guidelines are available upon request. US citizens must include their Social Security number with submitted manuscripts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by Wayne Green Inc., 70 Route 202 North, Peterborough NH 03458. Entire contents ©1993 by Wayne Green Inc. No part of this publication may be reproduced without written permission of the publisher. For Subscription Services, write to *73 Amateur Radio Today*, P.O. Box 7693, Riverton NJ 08077-7693, or call 1-800-289-0388. The subscription rate is: one year \$24.97, two years \$39.97; Canada: \$34.21 for one year, \$57.75 for two years, including postage and 7% GST. Foreign postage: \$19.00 surface or \$42.00 airmail additional per year. All foreign orders must be accompanied by payment in US funds. Second class postage paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #95656. Canadian GST registration #125393314. Microfilm Edition—University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateur Radio Today*, P.O. Box 7693, Riverton NJ 08077-7693.

Contract: By casting your baby-blues on this miniscule type, you have just entered into a legal and binding agreement with the staff and management of *73 Amateur Radio Today* to do something nice for a newcomer to ham radio. The nicest thing you could do would be to spend a measly \$12.97 and buy them a subscription to *Radio Fun*. That will help them get the most out of their new hobby.

NEVER SAY DIE

Wayne Green W2NSD/1

Radio Fun

Once it was clear that the no-code license was finally going to get by ARRL's stone wall, it looked as if we'd be seeing some growth in our hobby at last. That suggested three options, as far as publishing 73 was concerned. The information needs of newcomers are quite different from those of the older timers, so it would be difficult to make one magazine fit these contrary needs. Option one would be to ignore the newcomers and continue 73 unchanged. Option two would be to split it, trying to serve both groups of readers the way *QST* is doing. Option three was to go for option one and start a completely new publication totally dedicated to the needs of newcomers.

I chose option three.

To keep costs down I opted for tabloid format instead of the 73 size. This new size made use of newer typesetting systems, lower-cost presses, and much lower cost paper stock. You've probably noticed that most new publications are going for the tabloid format. I also like the flexibility of page designs the larger page provides, plus the ability to provide advertisers with more space to tell their sales story without having to charge them more.

Radio Fun was started a year and a half ago and has not just survived, despite a serious business recession, it's thrived. The reader feedback has been most gratifying. I suppose the one thing that has surprised us more than anything else is the number of older hams who are subscribing. The publication is aimed at helping newcomers not just get going in our hobby, but to discover the fantastic number of activities we have available. We mean the *fun* part, so we urge newcomers to try satellite communications, packet, RTTY, slow-scan, and so on. We want to help them get involved with club activities, to participate in contests, to get their higher-grade licenses and find out about working DX . . . perhaps even go on some DXpeditions! We want them to try traffic handling, working aurora skip, and experiment on our microwave bands. What we don't want is for them to get bogged down into a deep rut and lose interest.

There are antennas to erect, kits to build, new bands to explore, new equipment to buy and enjoy. There are flea markets, hamfests and conventions. There's even Dayton! And our

newcomers need all the hand-holding they can get to help them discover all of the wonderful things we have in store for them. How many transmitter hunts have you participated in? I guarantee you'll never forget one single hunt you get involved with. It's like going on a DXpedition . . . I've operated from a bunch of rare countries and I don't think one minute of those experiences will ever be forgotten. Navassa (twice!), Jordan, Afghanistan, Iran, Nepal, Syria, Swaziland, Lesotho, New Caledonia, Fiji, Western Samoa, American Samoa, Wake Island, St. Pierre, Thailand, Korea, South Yemen . . . oh what a flood of memories! How about moonbounce? Too difficult, eh? Not for hundreds of hams around the world.

Since about 75% of all ham equipment sales are to newcomers, the advertisers in *Radio Fun* have been cleaning up. Many tell us that they are getting far more sales via their ads in *Radio Fun* than in *QST*! And that makes sense when you see the readership statistics. Every ham newcomer gets *Radio Fun*, while only a small percentage of the newcomers are subscribing to *QST*. As a publisher, I love to see our ad sales steadily increasing. Does that mean I'll be buying a company jet? Nope, it just means that the publication will be thicker and have more articles on fun things to do and how to do them.

It also means that we need more people to help us turn out two publications instead of one, so we're interviewing for help with technical editing, advertising sales, circulation management, and all the other chores involved. We're putting *Radio Fun* out on a Macintosh desktop publishing system, which is easy to learn and fun to use. I don't know of anything we're doing where a college degree would be of much help, though an ability to read and write does come in handy. If they had a college course on meeting deadlines I might respect colleges more. But don't get me started on our lousy American educational system!

Radio Fun, like 73, is written largely by the readers. It's intended to be a communications more than an entertainment medium. If your club licenses a bunch of new hams, we want to publish a picture so we can spark more clubs into doing the same. We have far too many stick-in-the-mud clubs that need to be woken up. If you design a new piece of gear you can en-

courage others to duplicate your effort, as well as protect your idea, and perhaps even attract a manufacturer or kit supplier by writing it up. If you get involved with a new aspect of the hobby, such as satellite communication, keep notes of your successes and disasters and write it up. You'll help others to avoid the pitfalls, and perhaps inspire a few more hams to get involved.

If you buy a new piece of commercial ham gear and think others should know how much fun you're having with it, write it up. If you come up with some modifications or find some accessories, let us all know what you've done.

I don't know about you, but I don't trust most of the equipment reviews I read in the other ham magazines. They don't tell me the things I want to know . . . like what's new and different about this unit . . . what fun I am going to have with it . . . how difficult it is to get going. Things like that. I want to know how it does in the average hamshack, not at the hands of some professional writer who has more of an interest in pleasing the manufacturer than in leveling with me.

What's great about it? What's not so hot? How easy was it to set up and use? How does it compare with what you were using before? Make sense? The no-code ticket has doubled the number of newcomers, and if you can get your club to spread the word in your area we might be able to double that again. Some clubs are doing a fantastic job of recruiting newcomers. And contrary to the nabobs of negativism, these newcomers are busy learning the code so they can upgrade. The only bright side when it comes to our abundance of grouchy old-timers is that this attitude suppresses their immune systems and at least earns them their "Silent Key" award earlier than if they were fired with enthusiasm to try new things and help newcomers.

If you're not getting *Radio Fun* yet, foresooth! You can repair this serious oversight on your part by calling 800-257-2346, credit card in hand, and getting rid of a crummy \$12.97 for a whole year of fun.

About Perot

He says he's looking for good ideas. Well, my book has a ton of them, many of which have been covered in my editorials down through the years. The problem is, how can we get

H. Ross to read the book? Yes, of course I sent him a copy, but there's no sign that it ever got through to him. He's worried about the deficit. Fine. I proposed a whole new approach to solving this. He's concerned about our educational system and is looking for ideas for fixing it . . . which I've got. I propose a creative way to cut the cost of crime by about 80%, our health care costs even more than that, government expenses by 50% in five years, and so on. If you get a copy of my book, I think you'll be as excited as those who have already read it.

But how can we get through to Ross? He seems to be as insulated from the public he wants to work for as the President. Yes, I have a sneaky plan, but I need your help. Yes, you.

If you'll check out the bind-in cards in this issue you'll find one addressed to H. Ross. Tear it out, stamp it, and let's inundate him with cards. That oughta get his attention. Please note that I've left room for you to add a message of your own. Tell him what you think is the most important problem he should tackle . . . or perhaps force Clinton to tackle.

Don't let me down on this.

Dayton—Or Not?

When the invitation came asking me to speak again at Dayton, instead of automatically saying OK I gave it a good deal of thought. What are the benefits . . . to me . . . to those who spend an hour or so listening to me?

Yes, I know I usually pull a good crowd. But my interests seem far from those of most hams these days. I'm worried about America's future, and this means generating a high-tech work force for the 21st century . . . and that, to me, means the need for attracting a million youngsters to our hobby as a way to get them personally involved with technology. And in this I know I'm at odds with most hams . . . who prefer to keep our hobby as secret as possible for the enjoyment of a small, white, old, elitist group. I sense little interest in even worrying about the future, much less in trying to do something about it. It's a matter of enjoying ourselves now and to hell with all that crap about kids.

So that puts me in the role of a scold . . . and no one likes a scold. But I don't feel like I'm getting anywhere trying to interest hams in exploring the fun aspects of our hobby. When I talk about the fun of hidden transmitter hunts, instead of eyes lighting up with excitement, I see annoyance. When I talk about the fun of operating from some weird country on a DXpedition, I see eyes all over the room blinking out like Orphan Annie and Sandy, the oldest living dog in history. When I talk about the fun of experimenting on 10 GHz, making contacts from mountaintop to mountaintop, I see people leaving for more interesting talks, whatever they are.

Sometimes I talk about entrepreneurship and getting rich. This at least keeps people awake. There are so many opportunities to make big money that I get discouraged trying to cheer people on to at least give a try for the brass ring. In my book (*Declare War*) I suggest a bunch of ideas for

Continued on page 66

LETTERS

From the Hamshack

Ralph Dittmer KB9BRV, Mundelein IL. Because winter is such a dull time of the year, I decided to buy an inexpensive radio kit and build it in my spare time. I don't have much belief in most advertisements, so it was hard to decide which kit I should purchase. Most kits are way out of my price range, and I have found that the quality of many kits leaves a lot to be desired, except for a few. Also, I wonder how young amateurs can afford to build a transceiver or even a transmitter.

Anyway, I read 73 over and over again until I decided to purchase a kit from one of your advertisers, Lectorit, out of Sandusky, Ohio. When I first opened the package, I got the impression that this radio would never work very well. I proceeded to build it as the instructions said. Even if I had never built any radio, it is almost impossible not to have success with this one. The instructions are foolproof, and it is wonderful to have simple, complete, systematic steps to follow.

I do not know and have never met anyone from Lectorit but I do think these people should be congratulated for giving average-income earners a chance to be a part of amateur radio, and to build and operate a transceiver. I had my first contact with this set within 10 minutes after I completed building it. I have since had many QSOs. Thanks, 73, for pointing me to a real honest and affordable product. Also, thank you Mike Agsten WA8TXT for a nice product. Keep up the good work, 73. I will continue to subscribe, knowing that your advertisers are interested in the "everyone" in amateur radio.

Richard Bill N8ACI, Allegan MI Wayne, I have to apologize that I haven't looked at any of your magazines for a long time. Recently a friend called attention to your editorial in the August 1992 issue of 73. I am in tune with your feelings about the government-controlled educational system in this country. My background is about 19 years as an electronic engineer, most recently specializing in electromagnetic compatibility. About a year ago, due to some company politics and subsequent reorganization, I found myself out of work and over 40, thus virtually unemployed in west Michigan, where I live. This is perhaps one of those blessings in disguise, for I have been relying on a talent that I discovered through ham radio: teaching. I teach math, electricity, and electronics. My observation is that not only do our schools teach irrelevant subjects but, even worse, the system (including teachers, administrators, parents, and student peer groups) provides a very good education in an undesirable area. Even in "middle-class" areas, somewhere between about four years old and junior high school our kids learn to be afraid to learn and experience un-

derstanding. This appears to be especially true in areas of reading and technical-sounding topics like electronics, physics, and others. When I teach I strive to eliminate those fears and to open the door to real understanding, in part by making the topics relevant to the students' environment and personal goals. The longer this continues, the deeper trouble our nation gets into. My goal is to eliminate these fears introduced into real education. As a nation we can't afford to waste a lot of time getting started. It's going to take some time to turn things around.

Ray Stommel N7QAK, Seattle WA After two years, I am letting my 73 subscription lapse in April, and I want to tell you why.

It's an interesting magazine, but I don't give a hoot about building equipment from scratch, nor do I care about ATV or packet. So, that doesn't leave much in most of your issues for me.

I do care about DXing, rag-chewing and operating techniques, but 73 has precious few articles along this line.

Memo to Wayne: We finally received a negative letter for the "Letters" column. It seems that people who don't care about building or any of the newer fun modes don't care about 73. I guess there are other magazines for hams like this—hams who stopped learning and trying new things the day they got their license . . . David N1GPH

Ray, you're right. We should stop trying to get hams to try new things like packet, ATV, OSCAR and RTTY and concentrate on making them better able to chase ops in rare countries off the air (DX awards) and better able to spend the rest of their lives talking about nothing. But we do need to rewrite the regulations for this. Maybe you should take up golf, at least you'd get some exercise . . . Wayne

Gary Wagner VE7RLD, Kamloops, B.C., Canada Wayne, I just finished the February 1993 issue of 73—"Never Say Die" first, of course. I enjoy your editorials and, although they may not be what I want to hear, they all make you think! On page 76, at the end of "NSD," you have a section titled "In A Rut?" I read that with interest as you seem to have done a lot. How about this: You write that you are health conscious and healthy—how about a Shuttle flight? Imagine the contacts! I'd like to be one of them.

73 is great—keep it up. I hope to QSO one day. W2NSD/1 would be a #1 QSL card in my books.

Gary—Shuttle flight? Lordy, that would be something to brag about! Imagine using a \$23 million crapper! But why would I want to go into space

just to make a zillion 30-second contacts? Working pile-ups is okay for a few years, but even that pales after awhile and one's interest turns to looking for interesting people to talk with, and talk at length.

You say you'd like to QSO one day . . . well, that's what a letter can start. But what would we talk about? What are your areas of interest and expertise? What can you tell me that I'll find interesting? I don't want to be just a trophy to show off; I'm an interesting person to talk with and would prefer to be prized for that rather than for my location or "fame." When you want people to do something, the first step is to show them the benefit of doing what you want them to do.

I've flown around the world, visiting 25 countries as I went, and operating 20m SSB from the plane over the whole trip. I've DXed from about 65 countries so far. It would be exciting to go up in the Shuttle . . . and they'd be able to say that a 70-year-old man survived the trip (wow!). Other than that, I'm not sure of the benefits to NASA. I'll think about it . . . Wayne

Joe Mott K2UZK, Binghamton NY Wayne, after reading your August 1992 editorial and being completely in agreement with your ideas, I'd like permission to copy and distribute it to my NY State representatives as well as my federal money spenders in the feeble hope they might get some inspiration and consider some of your ideas.

Sure, give it a try, and let me know what response you get. I probably should go 50/50 on the cost of my book for anyone interested in sending copies to politicians . . . Wayne

Dan Hunt N4XAK, Chesapeake VA Wayne, I originally wrote to you back in late August, asking for ideas for a (less and less each day) disabled ham to open a business. I was pleasantly surprised at your quick response. However, you advised me to get into desktop publishing, using a Mac such as your PowerBook. Now, in the latest issue of 73, you reveal that my nads will be fried by 25 mG. With pals like you, who needs enemies?

All kidding aside, I had wanted to write and thank you for the ideas if I finally took the plunge. Well, I took the plunge, but wound up going into a wholesale/retail business for environmentally sound automotive products. My wife (N4XAM) and I are the sole owners. Much of the courage to do it came from reading your editorials, so we really appreciate the monthly pep talks. (We'll appreciate it more when we begin to turn a profit!)

Your monthly pep talks also encouraged me to volunteer to act as a mentor for an after-school technology club at one of the local schools. Most of the kids were acting like the club was something that parents had forced on them when I started my first meeting with them. By the time we were done,

they were all bright-eyed and excited about model rocketry. I built and had the kids fly a model rocket. Now they want to build and fly rockets of their own. Future sessions with them will include a trip to a natural museum, flying radio-controlled aircraft, building and flying model rockets, and amateur satellite communications. Thanks for encouraging me to do that as well. I don't know who's more excited—the kids or me!

So use your PowerBook on a desktop and irradiate that. That's what I do. And on planes I irradiate the tray table. Tell us more about how you're poisoning those poor little kids' minds with technology . . . Wayne

Dick Gobel K1CEN/0US, Fairbury NE Wayne, I just want to say how much I enjoyed your September 1992 editorial. Your comments about how socialism is destroying our country were exactly right. You reminded me of a quote I read some 40 years ago: "Never in the history of the world has a country, once started down the road to socialism, ever successfully restored its democratic form of government. Instead, it's ceased to exist."

Robert Mayer N9MRJ, Bartlett IL I have been a police officer for almost 19 years now; prior to that I was in the communications/technical end of law enforcement. After reading Sergeant Beegan's letter in the February 1993 issue, I came away with the impression that officers using radar for speed enforcement were frying birds in mid-flight and burning the hood ornaments off of passing cars.

Maybe he should have noted that law enforcement radar operates at 100 mW or less of power output. It was interesting to note that an article in the same issue, "Fun at 10,000 MHz," proposes operating at a frequency very near the law enforcement radar band at twice the power. If Mr. Beegan wishes to ban law enforcement radar for the reason that it is dosing people with radiation, frying birds and burning holes in Buicks, then the amateur radio service will also suffer the loss of those frequencies.

With the radar units currently in use, most of the officers don't even keep them on all of the time for the simple fact that many motorists have radar detectors. With a quick flip of a switch, the unit is shut down until the next vehicle's speed is checked. No fried birds or Buicks.

I do agree that we should keep after the power companies and the politicians to come forward with the facts, and not continue to act like there is nothing wrong. Facts are what we need, not vague accusations and finger pointing.

The Intermittent use of radar shouldn't do enough harm to measure, but there is plenty of evidence (facts) that prolonged use can cause serious problems for officers . . . Wayne

License Processing Delay Easing

The amateur radio license processing time delay appears to be easing a bit, according to Gordon Girtan W6NLG, who administered the Sunnyvale VEC in Northern California. Girtan says that he made a check with the FCC's Gettysburg License Processing Facility the week of January 14th and found that the processing time had dropped from the 90-120 days announced by the FCC just before the Christmas holidays to around 60 days in mid-January. W6NLG says that the FCC has processed license applications that it received on November 23rd, and that new licenses were expected to arrive on the West Coast by Monday, January 18.

Girtan noted that at Processing Level 1, the FCC has now processed all Form 610 applications that arrived prior to December 2nd. He also says that his VEC operation ships all completed applications to Gettysburg using Federal Express to minimize delay. Since many VE teams and VEC operations use standard US Mail as their delivery carrier, further delays of a few to several days are still possible. *TNX Westlink Report #642, January 28, 1993.*

Amateur Radio Scholarships

The Foundation for Amateur Radio, Inc., a nonprofit organization with headquarters in Washington, DC, plans to administer 47 scholarships for the academic year 1993-1994 to assist licensed radio amateurs. The Foundation, composed of 50 local area amateur radio clubs, fully funds five of these scholarships with the income from grants and from its annual hamfest. The remaining 42 are administered by the Foundation without cost to the various donors.

Licensed radio amateurs may compete for these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled in or have been accepted for enrollment at an accredited university, college or technical school. The awards range from \$500 to \$2,000, with preference given in some cases to residents of specified geographical areas or to the pursuit of certain study programs. Clubs are encouraged to announce these opportunities at their meetings, on their nets, during training classes, and in their club newsletters.

Additional information and an application form can be requested by letter or QSL card, postmarked prior to April 30, 1993, from: FAR Scholarships, 6903 Rhode Island Avenue, College Park MD 20740. The Foundation for Amateur Radio, incorporated in the District of

Columbia, is an exempt organization under Section 501(c)(3) of the Internal Revenue Code of 1954. It is devoted exclusively to promoting the interests of amateur radio and those scientific, literary and educational pursuits that advance the purpose of the Amateur Radio Service.

ARRL Files Automatic Control HF Packet Petition

On February 1, 1993, the American Radio Relay League formally requested a final extension of the *Special Temporary Authority (STA)* which currently authorizes certain amateur radio stations to conduct HF digital communications under automatic control. The present STA was first issued July 7, 1987, and has been extended five times. It expired on February 3, 1993.

The League asked, however, that the STA's termination be delayed until the FCC acts on their Petition for Rulemaking (also filed February 1st) proposing permanent rules governing HF data operation under automatic control. The ARRL said they "... firmly believe that the petition will be supported by the amateur radio community as a reasonable accommodation for all concerned ..."

The petition, which has not yet been assigned a Rule Making file number, seeks to permit automatic control of RTTY and data communications in certain small segments of the 10, 12, 15, 17, 20, 30, 40 and 80 meter ham bands. The ARRL said internationally agreed upon band plan changes made the proposal both workable and acceptable to the majority of ham operators.

The League's petition runs to some 35 pages. The following is a capsule version of the points made by the ARRL.

(1.) The League's goal in submitting the petition is to encourage experimentation, development and refinement of modern automatically controlled data communications ... and to improve emergency and public service communications.

(2.) The National Telecommunications and Information Administration agrees that the Amateur Service performs a vital role in adapting complicated and expensive technologies to useful communications systems. NTIA is the White House advisor on telecommunications matters. Digital communications networks are advancing at a rapid pace.

(3.) Current data operation in the HF bands includes RTTY, AMTOR, and packet radio. The Amateur Service is also experimenting with such new spectrum-efficient error-correcting digital modes as "Clover" and "Pactor."

(4.) The current rules do not permit automatic networking below 50 MHz and third

party communications must use the AX.25 packet protocol. This requirement was based on an ARRL proposal ... although many amateurs also want automatic high frequency networking authority as well.

(5.) The FCC was properly concerned that automatic "robot" stations will interfere with locally controlled users on the high frequency bands. Several petitions for reconsideration were filed. The ARRL suggested that a small group of data communications enthusiasts determine the feasibility of permanent HF data communications.

(6.) The first STA request was granted in 1987 for a six-month period and has been renewed ever since. HF packet works well, moves traffic—and, with careful frequency selection, provides a public service without undue interference to other amateur activities. But HF packet radio is not compatible with other modes and need separate frequencies.

(7.) The League proposed a plan (RM-7248) in early 1990 that would permit automatically-controlled HF data communications based on a new IARU Region 2 regional band planning effort.

The *International Amateur Radio Union* (IARU) is the worldwide union of national amateur radio societies. It is an international organization that is recognized by the ITU as representing the amateur and amateur-satellite services throughout the world. It is comprised of 126 member societies and is organized into three Regions corresponding with those of the ITU.

The ARRL petition was withdrawn two months later to consider other options for automatic control. These options would be developed through the work of a committee of interested amateurs.

(8.) A January 1992 *QST* survey on automatic digital communications gathered more than 500 responses which were considered by the League's Board of Directors at their meeting in July. It was clear that there should be no band-wide automatic control of HF digital messaging ... any such operation should be within specific subbands. "The League was faced with the dilemma of its obligation to comply with the band plan for such established by international agreement, and the rejection of the same by United States amateurs."

(9.) The ARRL Board elected to support a plan which would not permit automatic HF data communications between, or among, themselves. Rather, such stations would be limited to communications with stations under local control. The compromise semi-automatic control was criticized as unworkable and unacceptable by HF packeters.

(10.) Once again the League's Executive

Mini-Quad Loops

Three-fifths-size loops with full-size performance.

by Dean Frazier NH6XK

Eventually a ham discovers the gain, and especially the quietness on receive, of loop antennas, and plans to construct one. Soon enough it becomes apparent that loops for the bands below 20 meters are impossibly large. A square loop on 40 meters (7.15 MHz), for example, needs sides about 35 feet long, which may be unreasonably large to erect, especially in the vertical plane. However, a loop, or any antenna, can be made physically smaller while maintaining full electrical size. This can be accomplished with loading coils, as is frequently done in mobile applications. Unfortunately, coils do introduce some loss. Another approach is to reduce the size of an antenna, e.g. cause it to be resonant above the desired frequency by mechanical shrinking, and then capacitively "stretch" it, so as to achieve the proper electrical length for resonance. The latter is the approach taken here.

The mini-quad loops described are not quite three-fifths full size, and yet, via capacitive loading, are electrically stretched to a full wave. We don't get something (size reduction) for nothing, however. We do suffer some reduction in bandwidth, and we lose about 1/2 dB compared to the performance of a full-size loop. The former limitation may only be a problem on the higher frequencies, for which bands a mini-quad loop can be tailored for a specific portion of the band. Note that the 2:1 SWR bandwidth on 12 and 17 meters (Table 1) and 30 meters is greater than the entire width of the band. Regarding the second limitation, recall that a very good human ear just might detect a 1 dB difference in received signal . . . clearly a 1/2 dB reduction with a mini-

Figure 2. a) Feeding the mini-quad loop for horizontal polarization. b) Maximum radiation is off of the plane of the loop.

quad loop goes unnoticed. Contrast the "cost" of a loss of 1/2 dB, and some reduction of bandwidth, against the "gain" of a 40% size reduction. Add to this the forward gain (when mounted vertically) of several dB, and side rejection, and the mini-quad loop begins to look pretty good.

For low-angle radiation, the loop works best when mounted vertically and fed at the bottom, but if this is not possible, mount it horizontally and you can still communicate better than with a dipole. (Inspection of radiation patterns shows that while there are low-angle lobes for a mini-quad loop when mounted vertically, there is also considerable radiation in the plane of the loop. Many hams believe full-wave loops only radiate perpendicularly to the loop plane. This is just not so, and my personal experience confirms this.)

Mounted in the vertical plane, you'll have to arrange to rotate (point) the broad side of the loop; horizontally mounted, the radiation is omnidirectional. (Height and visual impact restrictions in my planned neighborhood preclude my outdoor loops being vertical . . . but I've had good success with them mounted more or less horizontally on the roof with a few inches of "standoff," and also

hung vertically on walls in the house. With a mini-quad loop on my living room wall inside the house, I have communicated as far away as Minnesota from Hawaii, with 5 watts on 12 meters.)

Construction

The dimensions shown in the tables are for wire mini-quad loops, 2-40 meters. Parameters S, p, q, and m are defined below:

S = side length, feet (The loops are square.)

p = capacitance hat inset, feet

q = capacitance hat length, feet

r = capacitance hat fold-in leg, feet

(Or inches if so specified.)

See Figure 1.

For the ambitious (those desiring to build a mini-quad loop for 80 or perhaps 160 meters, or for tailoring for a different portion of a band, such as 10 meters) the following formulae are provided:

$$S = \frac{147.917}{f(\text{MHz})} \text{ feet}$$

$$p = 0.128 \times (S) \text{ feet}$$

$$q = 0.774 \times (S) \text{ feet}$$

$$m = 0.304 \times (S) \text{ feet}$$

I feed the mini-quad loop with 50 ohm coax from the rig, terminating in a quarter wave of 75 ohm coax at the antenna feed point. For example, on 40 meters, 7.15 MHz, with 75 ohm coax (Velocity Factor = 0.75), a quarter wave is:

$$\frac{246(0.75)}{7.15 \text{ MHz}} = 25.804 = 25' 9 \frac{5}{8}"$$

See Figures 2a and 2b.

At the feed point, one end of the loop connects to the 75 ohm coax center conductor, the

Copper Dual-Band Super J-Pole Antenna

Build it in less than an hour.

by Marty Gammel KAØNAN

While looking for an antenna project to build I remembered seeing a Marine antenna called the Super J-Pole in the 1988 *ARRL Antenna Handbook*, which claimed a 6 dB gain over a quarter-wave ground plane. I didn't have a machine shop at my disposal to fabricate the parts shown in the Marine antenna article so I set about redesigning the antenna using materials that were easy to find and work with. I have had very good results working with copper J-poles, so I built my refined version of the classic J-pole. I then added a short insulating section, the extra half wave of vertical length, and the needed half-wave matching stub.

Materials

All the materials except the SO239 fitting can be found at any good hardware store, and the

whole antenna can be made in less than one hour.

In my design I use 1/2" copper schedule M tubing and 1/4" soft copper tubing. I had experimented with using a Teflon insulator, but have since changed my design to use a 9" length of hardwood dowel with three coats of lacquer as the insulator, for more strength.

Clean all the tubing, and then from the 1/2" tubing cut one piece each of the following lengths: 57-1/2"; 38"; 19"; 2", and a piece about 3" long for a stub to mount the antenna. In addition to the tubing, buy a 1/2" elbow, a 1/2" Tee, two 1/2" end caps, a 1/2" threaded fitting, and a cast iron floor flange for mounting. Get a piece of 3/16" or 1/4" soft copper tubing 42" long. Find the center of the 1/4" tubing and bend it around a 1"-to-1-1/4" diameter water pipe or dowel.

Put the Heat to It

Now fire up the torch and start the assembly process from the bottom up. See Figure 1. Use flux on all joints, solder the 1/2" threaded fitting to the mounting stub, and solder the 1/2" Tee fitting. Then proceed with the 57-1/2" section, 2" cross piece, and 19" section. Pay close attention to getting the 19" piece parallel to the 57-1/2" piece. After these have cooled, drill through both the 57-1/2" section of 1/2" tubing and the hardwood dowel about 1/4" from the top end of the 1/2" tubing, and the bottom of the 38" section of tubing. (See Photo A.) Then insert the 1/4" tubing through the 1/2" tubing and dowel assembly. Sweat solder the 1/4" tubing to the 1/2" tubing and sweat solder the end caps. After these have cooled, clean the entire antenna, bend the half-wave matching section to a half circle of about 4" radius around the antenna to help the balance and match.

Simplify the Feed Point

The feed point also needed to be made simpler, so I elongated one of the mounting holes of a panel mount SO-239 fitting and inserted a stainless steel adjustable band clamp. This goes on the 57-1/2" long section of 1/2" tubing. A short 2-3/4" length of #14 copper stranded wire is soldered to the center terminal to go over to the 19" section. I used another stainless steel clamp to attach this. (See Photo B.) While experimenting to find the proper feed point, I found that the distance above the crossbar should be about 3".

Building Suggestions

1. You may use a Fiberglass rod as an insulator, but you will have to be very careful with the torch or you may weaken or burn the rod, or make it brittle.
2. When cutting the 1/2" copper tubing, cut the 57-1/2" piece from one end of the 10' length, and the 38" piece from the other end. By doing this you will have factory-cut edges for inserting the 1/2" dowel.
3. Be sure to keep the flame of the torch away from the insulator to avoid burning it.
4. Use paste flux on all joints when fitting the pieces together. Use enough flux, since you will be cleaning the entire antenna with solvent after assembly.
5. Use a weight to hold the 19", 57-1/2", and 2" pieces, and the Tee and the elbow, flat when they are sweat soldered together.
6. Use a ruler or caliper to check the spacing

Mini Quad Loops

Continued from page 10

other end to the braid side. Or, you can use an S.O. connector mounted in a convenient manner (I use PVC strips).

Apartment/Condo Dwellers and/or New Hams

See Table 1 for 10 meter dimensions, Table 2 for 2 and 6 meter dimensions.

It is a simple project to mount a mini-quad loop on the wall or ceiling in an apartment, or in the attic of a house. A loop can easily be set up around a picture frame. Small wire, two

or three inches of standoff from the wall, some white paint, and/or curtains or a large picture, etc., can be used to make the loop invisible and yet still be effective.

Summary

You'll get 2-3 dB gain over a dipole, and notice much quieter reception. Build the mini-quad loops according to the dimensions supplied. Trim the capacitance legs only as necessary to achieve resonance (lowest SWR at feed point) if metal, wiring, wood, etc., in the near field of the loop cause detuning. The mini-quad loops can form the driven elements of two- or three-element cubical quad beam antennas.

Quad loops don't have to be large to be good performers. And they are "quiet."

NOTE: Mini-Quad-Loops have been constructed, tested and used on 2, 12, 20, and 40 meters, with the data of Tables 1 and 2, with good results. Initial SWRs in all cases, at the feed point, were at worst 1.5:1. Adjustment of the angle between p and m allows improvement in SWR. In each of these cases the relationships for S, p, q, and m given in the text worked—e.g.:

$$S = \frac{147.917}{f \text{ (MHz)}}$$

The table values for 5, 10, 15, and 30 meters are derived, but based on the experiments on 2, 12, 20, and 40 meters. I have no reason to believe that the derived data is not good data.

OAK HILLS RESEARCH QRP Headquarters

QRP SPIRIT CW TRANSCEIVER

- Single band transceiver kit offered on 80, 40, 30, 20, & 15 meters
- Iambic keyer included using latest Curtis Keyer Chip 8044ABM
- Superhet receiver design with diode ring mixer & RF pre-amp
- 4 pole crystal ladder filter followed by an on board audio filter
- Switchable HP AGC circuit with manual RF gain control
- 2 watts of audio output w/external speaker jack
- Vfo tuning with 8:1 vernier dial covering 100 KHz and RIT
- Sinewave sidetone oscillator w/frequency & level controls
- Silky smooth QSK circuit
- Full 5 watts of RF output on all bands
- 12VDC operation
- Measures (HWD): 4" x 6 1/4" x 6 7/8" and weighs 47 oz
- 100% complete kit including cabinet, all components and instructions
- All coils are pre-wound. PC boards are quality double-sided with plated-thru holes (except keyer board) and component screen.
- Previous building experience desirable

between the 19" and 57-1/2" pieces, to keep them parallel to each other.

7. When drilling the SO-239 fitting, use a drill

press. Be careful not to drill into the threads of the fitting. After the holes are drilled, file the opening flat for a better band clamp fit.

Parts List

- 1 10-foot section of schedule M 1/2" copper tubing
- 1 1/2" copper elbow
- 1 1/2" copper Tee fitting
- 2 1/2" copper end caps
- 1 1/2" copper threaded fitting (for mounting)
- 1 1/2" cast floor flange (for mounting)
- 1 Piece of 3/16" or 1/4" soft copper tubing 42" long
- 1 Piece of 1/2" hardwood dowel or Fiberglass rod
- 1 SO-239 panel mount coaxial fitting
- 1 Piece of #14 stranded copper wire
- 2 3/8" by 7/8" stainless band clamps

Tools needed:

- Tape measure
- Tubing cutter
- Propane torch
- Solder and flux
- Electrical tape
- Caulking compound
- Screwdriver
- A weight to keep parts aligned while soldering
- Steel wool or a Scotch Brite pad (for cleaning all copper)
- Spray can of clear exterior lacquer (to finish-coat completed antenna)

8. After the best match has been found, you may want to solder the SO-239 and the stranded wire end to the 1/2" tubing.

9. When the antenna has been cleaned and matched, spray the entire antenna with a coat or two of clear lacquer to keep it looking nice.

10. After everything else has been done, apply silicon or a butyl rubber compound to the insulating section, then cover the joint with electrician's tape for a weathertight seal.

11. A 1/2" pipe coupling and a length of pipe may be used in place of floor flange for mounting in a roof tripod.

HR2510 Hi-Power Modification

Increase the performance of this popular HF rig.

by Carl Merrill

After reading the high power modification originally published in *73 Amateur Radio Today* ("Beefing Up the Uniden and the HTX-100" by M. T. Stacey KC4HGH, September 1989, p. 48) and then changed by the original writer (*73 Amateur Radio Today*, "Updates," November 1989, p. 76), I discovered another method that is easier to implement and has given consistent results.

The modification in the 1989 article and update requires you to change the output transistor from a type 2SC477 to a type 2SC497, then change the pre-driver transistor Q134 from a type 2SC2086 to a type ECG-340.

I found that the ECG-340 didn't really give any more drive to the driver transistor, for it is an emitter-follower, with a gain of less than one, so I left the 2SC2086 portion of the circuit alone.

The Modification

The following modification will give you marked improvement in the power output of the HR2510 and is easy to implement:

1. Change the output from a 2SC477 to a 2SC497 and make the necessary bias adjustments as follows:

Connect the radio output to a 50 ohm dummy load and set the frequency to 28.005 MHz, USB mode, with no modulation.

Hook up a meter (0-100 mA scale) between test points TP4 (+) and TP2 (-) to monitor final amplifier current.

Key the transmitter with no modulation and adjust VR112 for 80 mA collector current (Q132).

Place the meter's negative lead on TP3 and check the driver current.

Adjust VR113 for a driver current of 50 mA, if necessary.

Replace shorting bars into TP4, TP3 and TP2.

While tuned to 28 MHz, adjust the AM power output to about 5 watts by adjusting VR107.

3. Turn off the power and locate Q134, the 2SC2086 amplifier transistor. Cut the foil (as shown in Figure 2) to remove the

network from the emitter. Remove the 0.01 uF capacitor (C135) from the collector of this transistor to ground. Bridge the foil from the open end of the network to the collector foil. Now, solder the removed 0.01 uF (C135) to the bottom of the board from the emitter to ground. See Figures 1 & 2 for details.

4. Check your work carefully for any solder bridges and turn on the power. The AM output will normally jump up to about 15 watts after this modification. Turn the AM power output down to about 12 to 13 watts by adjusting VR107. This is plenty for this radio and will sound real nice on the air. You should find that the SSB power will now be around 25 to 32 watts.

5. Adjust the SSB output for peak power by feeding a single 1 kHz tone (or dual tone) into the radio while adjusting VR104 (the SSB ALC pot).

6. If your radio needs further alignment, consult the appropriate service manuals for the HR2510 and the HTX-100. The 2SC497 may be obtained from RF Parts, 1320 Grand Ave., San Marcos CA 92069. Tel: (800) 854-1927 (for orders only).

Results

The purpose of this change is to make the 2SC2086 provide gain, for in an emitter follower configuration, the gain is always less than 1. It works better, and saves the cost of the ECG-340. I have completed this modification on approximately eight different radios and they work fine. They can be heard in places they couldn't reach before.

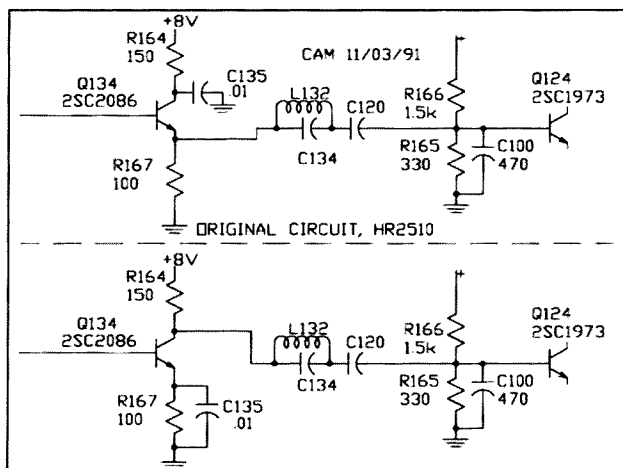

Figure 1. Modification for increased power for the Uniden HR2510. Top circuit is the original; bottom circuit is the modified version.

Figure 2. Modifications to the PC board, bottom view.

10 Meter X-Beam

Upgrade your antenna as well as your license.

by John E. Williams N5SJZ

After a year as no-code Techs, my wife Debby N5SKA and I decided it was time to upgrade to Tech-plus and work some DX. With help and encouragement from Joe Nunnamaker KD3VR, passing 5 wpm was much less of a chore than we had imagined. The big day was here and we had our 5 wpm Certificates of Successful Completion in hand; it was time to work the world.

I had previously purchased a small 10 meter rig and had put up a simple 10 meter horizontal dipole in anticipation of this day. Over the next few weeks, even though I made several contacts, I was not happy with the results. I felt it was time to upgrade my antenna. First I considered several commercial antennas. However, I had caught the bug for homebrewing with a 2 meter amplifier kit and had met Joe in the process, but that's another story. Since this was my first antenna project, I wanted it to be simple, high performance, and low cost. At first my criteria seemed mutually exclusive, but then I came upon an article in the *ARRL Handbook* by Brice Anderson W9PNE concerning X-Beam antennas. I spoke with Joe and told him my idea. He enthusiastically agreed to lend his expertise and help with the project.

Materials

I wanted to construct the antenna with materials I could locate at the local hardware store. So, with Joe and Debby, I paid a visit to the hardware store. For the X-beam arms, we considered aluminum and copper. We selected

copper tubing for several reasons. First, copper is less than half the price of aluminum. Second, unlike aluminum, copper can be soldered-to directly. And finally, copper has a lower resistance to radiation, perhaps giving a slight performance edge. For the center support we chose a 1/2" thick, 2' x 2' square pre-cut piece of plywood.

After purchasing the necessary materials on a Saturday, we planned to build and put the antenna on the air the next Saturday. All the materials for the antenna cost less than \$40.

Construction

The first step is to prepare the copper tubing and plywood. Cut the four 8' pieces of the copper tubing to 6'11" with a pipe cutter, then use extra-fine steel wool to polish the copper tubing to remove oxidation and let the beauty of the copper show. To ensure that the antenna will continue to look good and resist the elements, apply several coats of a spray-on acrylic protectant to the copper tubing. Prepare the plywood with two or three coats of weatherproof paint, allowing two

days of drying time between each coat. Next week, the plywood and the tubing will be ready to go.

The first step in actual construction is to draw an X on the center board where the copper tubing arms will go. After drawing the X, measure 2.25" from dead center on each line. This is where the end of each arm is placed on the board. Place the pipe brackets over one arm and use this arm as a guide for marking holes for the bracket bolts on each line. Next, drill the holes for the brackets and a 1.25" hole at dead center for the mast. If you are using a larger or smaller mast you should adjust the center hole size accordingly.

The next step is to drill a small hole on the

Figure 1. Top view, looking down.

Photo B. Close-up of the coax connector soldered to the driven element arms.

Photo C. Using plastic wire ties to secure tails to nylon supporting cord.

Photo D. Close-up top view of finished antenna center board.

center board between two arms. It makes no difference which two arms you choose at this point since they are all the same length. Route the pigtail coax connector (or plain coax) through the center board and solder the inner conductor to one arm and the outer braid to the other. These now become the driven arm elements. To ensure the best contact, clean the areas on the arms to be soldered with steel wool to remove the acrylic protectant previously applied. Since the weather was somewhat cold, we used a propane torch for soldering instead of a soldering iron. Since we were concerned that the paint would be blistered by the heat, we solved this potential problem by placing a double thickness of aluminum foil under the arms when soldering close to the center board. After soldering the coax connector, solder a heavy piece of copper braid to the other two arms. The arms connected with copper braid become the director arms.

Now that the driven element and director arms have been determined, it's time to solder the element tails to the ends of the arms. Since the element tails will not be under stress, we chose 16-gauge enamel-coated sol-

id copper wire instead of Copperweld wire. Start with each driven element tail 36" long and each director tail 30" long. If you use aluminum tubing or smaller gauge wire you will need to start with each element tail 12" longer to ensure that the antenna can be tuned. If using coated wire, carefully scrape away about 1" of the enamel coating at the ends of the wire to be soldered. To ensure a durable connection, bend the ends of the wires in 1", then solder them parallel to the arms.

To provide support for the element tails, use nylon cord strung through the ends of the arms. To prepare the arms for the cord drill two 1/8" holes, located 1/2" from the ends of each arm, parallel with the center board. Pass one length of nylon cord through the holes, pull it tight and tie it securely. Place the element tails beside the nylon cord and use plastic wire ties to secure them to the cord. The cord not only supports the element tails, it also strengthens the entire antenna structure.

Mounting and Finishing

Now it's time to prepare the antenna for mounting. For good strength use three L-

brackets to support the antenna. Place two brackets on one side of the center board and one opposing the other two. Start the L-brackets about 1" away from the edge of the center hole to allow for proper U-bolt placement. After marking and drilling holes, mount the L-brackets securely to the center board. After mounting the L-brackets, place the antenna mast through the center hole and secure the antenna to the mast with three U-bolts.

Now that the antenna is mounted, the next step is to form a current balun (RF choke). Form the balun by winding six turns of coax (directly below the center board) into a 6" i.d. loop. This keeps RF at the antenna and prevents stray RF from coming down the coax cable.

You are now down to the finishing touches to make the antenna last longer and perhaps perform better. Placing plastic wire ties around the coax directly above and below the coax feedhole in the center board will provide strain relief for the coax. Coax seal applied to exposed coax will keep water out and will prevent premature coax failure. Finally, to help ensure a longer life for the center board, apply touch-up paint to any small chips that resulted from drilling.

Photo E. Bottom view of center board. John making current balun (RF choke).

Photo F. Side view of current balun (RF choke) on antenna.

The final step before going on the air is tuning. First, remeasure each element tail. At this point the driven element tails are 36" and the director tails are 30". The driven element tails must be exactly 6" longer than the director element tails. If they are not the same, cut them to length. To tune the antenna, place it in its final position and measure the SWR. The antenna is tuned by taking the antenna down, cutting 1/4" off each tail, putting the antenna up, and remeasuring the SWR. It will most likely take several rounds of checking SWR, cutting the tails, and remeasuring SWR before the antenna is tuned. Our final measurement for each driven element tail was 34", while each director tail was 28". As shown in Table 1, the X-Beam antenna is usable from one end of 10 meters to the other! Since the tail lengths may vary according to the material used in the antenna construction, the antenna height, etc., it is much better to start with tails a bit too long and cut to size.

Performance

The X-Beam more than met my expectations. According to the *ARRL Handbook*, forward gain is about 5 to 6 dBd. Also, the angle of radiation seems very low. The first noticeable difference in performance was that we could hear many more DX stations than with the dipole.

Photo G. The finished antenna.

I have gotten reports of 2 to 3 S-unit differences from both stateside and DX stations, depending on where the beam is pointed. With only 25 watts, I have been able to work pile-ups to DX stations in Senegal, New Zealand, the Balearic Islands, Denmark and Japan, to mention a few. Now I have a fighting chance in pile-ups. Put one up and you will, too.

Parts List

4	Pieces 1/2" copper tubing, cut to 6'11" each
1	2-foot-square piece plywood
1 pint	Weatherproof paint for plywood
1 can	Spray acrylic protectant for tubing
15'	16-gauge copper wire
4"	Heavy copper braid
3	Heavy L-brackets
3	U-bolts
20	1/2" pipe clamps
40	Small bolts, 1/4" x 3/8"
9	Large bolts, 3/8" x 1"
	Nylon cord
	Plastic wire ties
	Coax-seal

AUTO-ID AUTOMATIC MESSAGE BROADCASTER

The **AUTO-ID** is a solid state digital voice recorder that was developed especially for 2 way radios. It simply plugs in between the radio and it's microphone. With the use of your radio microphone, you can record up to 5 separate messages that can be played on the air by pressing one of the 5 message buttons. The **AUTO-ID** also has a built-in timer that monitors your PTT (push to talk) activity. Record your station identification, and thereafter any time you are on the

air, the **AUTO-ID** will broadcast your ID message for you. The **AUTO-ID's** message #1 timer can be set for intervals of 3 or 9 minutes or it may be set to broadcast your message

every time you use your PTT. With the use of the **AUTO-ID's** built in speaker, you can monitor the message that the **AUTO-ID** is broadcasting, regardless of whether the selected message was broadcasted automatically or manually.

The **AUTO-ID** comes with plugs for an Alinco or Kenwood mobile amateur radio. There are accessories available to interface the **AUTO-ID** to most other types of radios.

FEATURES

- 12VDC power jack.
- Microphone patch cord (INCLUDED).
- 110VAC adapter (INCLUDED).
- Fully wired and tested, just plug it in.
- No soldering required.
- Built in local speaker.
- Adjustable speaker volume.
- Adjustable microphone level.
- Adjustable message broadcast time. (Message "1" only)
- Connects directly in line between radio and microphone.
- Pre-wired for Alinco and Kenwood Mobile radios.
- Power, Record and Play LED indicators.
- TX ready LED indicator.
- Timer enable/disable switch.
- All solid state construction.
- Up to 5 separate messages can be played individually.
- 32 seconds of total digital audio storage time.
- Simple to use.
- 1 year limited warranty.

The Ultratorch

A tool for liberation.

Master Appliance

P.O. Box 68

Racine WI 53401

Telephone: (800) 558-9413

Price Class: \$60-\$80 list,
depending on model.

I'm sure you know the problem. There is some trivial soldering task to be performed . . . out in your car, up on the roof, or under the hood of your car. You spend far more time messing around with tangled extension cords than it takes to do the work itself.

Or perhaps it's worse than that: You're bicycle-mobile, halfway up Slumgullion Pass In Colorado, chatting with a mountain-topper, when he starts complaining that your signal is intermittent. You stop to look, and you see it—the kluge antenna connection you kept meaning to fix has come loose at last. Do you try to hold it together with duct tape, or pitch camp and wait for an airlift?

Sometimes it's merely irritating—you're in your shop, crawling around some piece of gear, and your coffee sails off the corner of the bench when you tug on the iron's cord in a futile quest for that extra three inches. Argh.

It's a pain to be tethered, isn't it?

The Solution

Numerous cordless soldering irons have appeared over the years, both electric and butane. As a full-time nomad, I've tried them all with generally disappointing results . . . dreading on-the-road soldering tasks until now. Last year I finally found a portable tool that is actually MORE useful than any of my conventional lab soldering stations—the Ultratorch from Master Appliance.

The company offers a number of models, but my favorite is the UT-100Si (self-igniting). Available with 16 different tips plus a heat-shrink nozzle, this 10-inch, 5.5-ounce tool will change your life. I actually carry TWO of them on my bicycle: one permanently fit-

ted with the heat-shrinker, the other with a 0.5 mm tapered-needle soldering tip. They both see heavy use in labs and on the road. Using it is a simple matter of turning on the gas at a suitable level and pushing the built-in piezoelectric igniter button. After a few seconds it's ready for work—it's that simple.

Ultratorches run on standard butane and refill easily from the canisters sold in grocery stores for cigarette lighters. The self-igniting model gets about three hours of use on its mid-range heat setting. There is also a model without the igniter (the UT-100)—this gets

less running time per tankful, but has the advantage of a 2372-degree-F torch mode (the UT-100Si will do that too, but only with its relatively fragile innards exposed . . . not recommended).

I have found the power to be quite acceptable for all the usual hardware hacking and maintenance tasks, up to and including coax connectors and PC-board ground planes (using a larger tip, of course). At the low-wattage settings the tiny tip is comfortable around delicate circuitry, and the heat shrinker will pay for the tool all by itself. Quality is excellent, and various little touches indicate that the designers paid close attention to the needs of the market—like a flat area on one side to keep it from rolling away.

Another model in the Ultratorch line is the UT-50, a pencil-length unit (6" and 2.2 oz.) complete with pocket clip. It's not self-igniting, but it has all the other features, including torch mode. Though it only gets about 20 minutes on a charge, it fits just about anywhere and is comfortable around dense packaging.

I have probably burned over a liter of butane in my two units—over 100 hours of use. I've been on my back in a campground, fixing a bicycle wiring harness connector . . . deep in a prototyping project in a Silicon Valley lab, whipping up a switching power supply . . . under the hood of a diesel truck, grafting a power cable . . . on an antenna tower, fixing a preamp . . . all with Ultratorch in hand. If you have relegated the cordless soldering irons of yesteryear to the dusty recesses of your flea-market FOR SALE box, give the Ultratorch a try. You just may end up getting rid of your AC-only bench iron instead.

Lightweight, Collapsible Quad for 2 Meters

Excellent performance in a small package.

by Chester S. Bowles AA1EX

New England is blessed with numerous mountains and hiking trails. While our mountains aren't large by Western standards, they are interlaced with roads and trails that make them very accessible—a perfect opportunity for VHF/UHF mountaintopping trips.

I have been a licensed ham since 1967. However, when I purchased my first HT just a few years ago I discovered the pleasure of combining amateur radio with my occasional hikes through the woods. Of course, the elevation makes long-distance contacts easy. As an example, one of my most pleasant contacts occurred during a hike along the Wapack Trail, which has a trailhead just behind my house in Sharon, New Hampshire. Using the Mt. Greylock repeater in western Massachusetts, I had a long conversation with another hiker who was on the Appalachian Trail in Vermont. As we both huffed and puffed along our respective trails, we marveled at the technology that allowed us to communicate so easily across so many miles.

But using HTs on mountaintops presents some technical difficulties. Even using low power and a rubber duck antenna, keying the mike often opened up multiple repeaters. Hearing all those IDs come back was fun, but having any sort of contact was impossible. In addition, I was disrupting communications in multiple locations. The need for a directional antenna was obvious.

I began to think about various portable antenna options. However, my experience with directional antennas is very limited, so I invested \$20 in the latest edition of the *ARRL Antenna Handbook*. It was a wise investment. The book is filled with technical information, along with numerous construction ideas. After reading the appropriate sections of the book and talking with some ham friends, my design began to take shape. Construction and tuning, however, turned out to be more difficult than I expected.

I chose to build a quad because of its inherent light weight and because (I thought) no matching would be required. Also, in theory, a two-element quad has more gain than a three-element yagi, making the boom length shorter and therefore more portable. My basic design was good. Construction was simple, the antenna collapsed as expected, and the weight was acceptably low. I quickly discovered, however, that at VHF

frequencies the ratio between wire diameter and element length is crucial. Therefore, the formula for determining the length of a quad's driven element (1005/fMHz) did not work. Countless experiments with various gauge wires and element lengths left me no closer to success. I could not get the SWR below 2.8.

As it turned out, the solution was a simple stub-matching network using a trimmer capacitor. With that addition, the antenna matched perfectly, with SWR readings of less than 1.2 across the entire 2 meter band.

Construction

Construction of the quad is simple and takes very little time. Also, the materials are easy to find and inexpensive.

Start the construction by assembling the boom. The distance between the wire elements is not crucial; any length between 15" and 16" will work just fine. The boom consists of five pieces, as shown in Figure 1. The best approach is to cut two pieces of PVC piping, each about 7" long. Then assemble the boom and measure the distance between the spreader holes. Adjust the length of the boom by cutting off short sections of PVC piping until the total length is correct. Do not glue any of the connections or the antenna will not be collapsible. The parts will stay together by friction.

Next, drill 1/4" holes completely through the boom elements as shown in Figure 1. Note that one set of holes is in the coupling while the other set is in the 3/4" piping itself. This allows the spreaders to be rotated when collapsing the antenna. Drilling holes in PVC is perhaps the most difficult part of the construction. Use a nail or other sharp object to make an appropriate starting point

Photo A. The quad shown fully erected. Additional pieces of PVC piping can be added to the mast if more height is needed.

on the PVC. Then, drill carefully, making sure the holes are straight and perpendicular to the PVC. Otherwise, the spreaders will be crooked.

Insert the 1/4" dowels through the holes. I used nylon ties to hold the dowels in place. Do not cut the dowels yet. That will be the last construction detail.

Select one set of wooden spreaders to be used as the reflector element and, using the nylon ties, loosely secure one plastic ring to each of the four spreader ends. Then, loosely secure one plastic ring to three of the spreader ends that will be used as the driven element. The plastic ring is not required on the fourth driven element spreader because

Photo B. The quad shown fully collapsed and ready to be carried to your favorite mountaintop. Note the HT for size comparison.

the coax feed and the matching network will be installed on that spreader.

Cut the wires for the driven and reflector elements using the 18-gauge hookup wire. The driven element should be 82.5" (209.6 cm). The reflector should be 86.6" (220.0 cm).

Feed the reflector wire through the plastic rings on the reflector spreaders. Then strip about 1/4" of insulation from each end of the wire and solder the two ends together, making a complete loop. Position the plastic loops along the spreaders until you form a tight, perfect square (it helps to measure the distance along each spreader). Finally, tighten the nylon ties securely and cut the tails.

Construction of the driven element is more complex because of the matching network. First, feed the driven element wire through the three plastic rings on the driven element spreaders. Then, using a nylon tie, secure the driven element wires to the fourth spreader, as shown in Figure 2. Assembly and construction details of the matching network are also shown in Figure 2. Use caution when soldering to insure a good connection and to avoid overheating the components. Position the wire into a perfect square and tighten all the nylon ties, cutting the tails. Finally, secure the matching network and coax to the spreader using additional nylon ties.

A 30" piece of PVC piping serves as a short mast. Additional connectors and lengths of piping may be added to extend the mast if desired.

The only remaining construction detail is to trim the wooden spreader elements. Pruning shears work very well, but leave about 1/2" of extra dowel in case future adjustments are necessary.

Adjustments

Signals generated by a quad antenna are polarized. If you want vertical polarization, the antenna feed point must be on one of the horizontal spreaders. Conversely, if you want horizontal polarization, the antenna feedpoint must be on either the top or bottom spreader. The design of this quad allows the polarization to be changed easily—just twist the spreader elements 90 degrees.

Antenna matching is accomplished using an SWR bridge and tuning the trimmer capacitor to achieve the best reading.

To collapse the antenna, pull the PVC piping out of the "T" connector. Then, while holding the wooden spreader elements, twist the PVC piping and connector 90 degrees. The spreader elements will then line up in a package about 30 inches long. Of course, the wire elements will hang loosely at this point, but they will stretch back into shape when the antenna is reassembled.

I tested the antenna on several recent hikes. One hike took me up Mt. Monadnock in southern New Hampshire, and the second up Mt. Azischoos in northwest Maine. Performance was as good as expected. The antenna fit easily into a long, narrow bag that I could wear like a backpack. Assembly was easy and quick, taking less than two minutes. And, best of all, the signal reports were outstanding. Using less than 1/2 watt, I was easily able to work repeaters 60-70 miles away with full quieting. Using 3 watts yielded similar signal reports on repeaters more than 100 miles away. Simplex was fun, too. The gain and directivity allowed me to block

Photo C. Close-up showing details of the construction of the matching network.

side signals quite well and to work selected stations with ease.

A note of caution: This antenna was designed to be very lightweight and portable. As a result, it is fragile. The 1/4" dowels can easily be broken, so use care when handling the antenna. Also, the antenna was designed to be used in fair weather. The capacitor and the wooden spreaders should not be exposed to rain or moisture. A light coat of spray lacquer or silicone sealant would afford some protection. Finally, the capacitor can be bumped easily, causing the setting to change. A drop or two of clear fingernail polish will "cement" the capacitor at the proper setting.

Those cautions aside, the antenna performs extremely well and is easily carried on hikes or climbs. I'm sure it will afford much pleasure on your mountaintopping expeditions.

PARTS LIST

- 1 3/4" PVC pipe, 10 ft. long
- 2 Couplers for 3/4" PVC pipe
- 1 "T" connector for 3/4" PVC
- 4 1/4" x 36" wooden dowels (for the spreaders)
- 1 Package nylon ties
- 7 1/2" plastic rings (available at craft stores)
- 20' 18-gauge hookup wire
- 6" 300 ohm TV twin lead
- 1 Trimmer capacitor 6-50 pF (Radio Shack # 272-1340)
- Coax and connectors

Figure 2. Detail of matching network.

Want A Dish?

Building your own is easier than you think.

by Ralph E. Herzler WA8WBP

A homemade dish does not need to be a mathematical nightmare. The literature is full of complicated formulae that supposedly tell you how to construct the dish of your dreams. You need not be a rocket scientist to cut through all of this mish-mash. Allow me to take you step-by-step through the process.

Calculations and Construction

The usual first decision in designing a dish is to establish the desired diameter. The larger the diameter, the greater the gain of a dish antenna system. Most of us are limited by physical or other constraints to a maximum diameter. In my case, the space available on the rotating bar of my satellite antenna system limited me to a four-foot dish. Since some of my QSOs involved hams using a dish of this size on the frequencies that I wanted (1269 and 2400 MHz), I was encouraged to proceed.

After you determine a suitable diameter, the next choice is the f/D ratio, where f is the focal length of the dish and D is the diameter already determined. The focal length is the distance from the deepest part of the dish to the closest end of the feed system. Feed systems may be of several kinds and are another subject. Suffice that the recommended f/D ratios for amateur work are between 0.4 and

0.6. I chose 0.5, which gave me a focal length of 24 inches.

Knowing the focal length and diameter makes it possible to determine the depth of the dish. The only formula necessary is: $d = D^2/16f$, where d is the dish depth, D is the dish diameter, and f is the focal length, all expressed in inches. Thus, my four-foot dish with a focal length of 24 inches would be $48^2/16 \times 24 = 6$ inches. that is all there is to the math!

With guidance from Bob Douglas W5GEL, I built a dish based on these dimensions and similar to the construction project by Keith Berglund WB5ZDP published in the May 1989 issue of *73 Amateur Radio Today* ("Inexpensive Mode-L Dish Antenna"). Instead of using a formula to establish the paraboloid, I simply laid out a scale on 1/2" plywood marking 1" points from zero to six in one direction and 4" points from zero to 24 (the dish radius) in the other direction. Draw lines from the zero-zero point to each of the six 1" points. By joining the intersection of these lines and the six 4" points on the other axis, the contour of half the dish was established. See Figure 1.

Sawing this contour from the marked plywood will produce an excellent bending fixture, as shown in Photo A. I chose to use aluminum channel for the ribs and found it, called "half-inch plywood channel," at a local distributor. When one end is clamped to the fixture, you can easily shape the channel to the fixture by us-

ing a rubber mallet. There is some springback to the formed piece, which I corrected by hand. If I were to do this again, I would deepen the curvature of the fixture enough to compensate for the springback. However, hand correction is accurate enough for this frequency range and below. Higher frequency operation might be a bit more fussy.

In my application, I felt it desirable to build a lighter unit than that described in Keith Berglund's article, while maintaining his excellent methods of attaching the ribs to a hub and providing means to attach the 1" and 3/4" sections of pipe for counterbalance and feed support, respectively. The counterbalance, in my case, is a 24" length of pipe coupled to the mounting flange with a pipe tee. The tee's purpose is to introduce coax and other wiring through a length of 3/4" PVC pipe and carry it to the feed device. The length of PVC pipe is such that the hot end of the feed device is at the focal point, in my case 24". Each end of the PVC pipe is threaded with an extra-long thread to provide for adjustment to the focal length. By using this method of supporting the dish feed, I was successful in avoiding additional feed supports. However, be prepared for your hardware man to doubt your sanity when you ask him to thread PVC pipe, since it is usually glued.

In a further effort to keep weight at a minimum, I cut pie-shaped sections of 1/4" mesh hardware cloth to fit the rib assembly so that the factory-finished edge forms the outer edge

Photo A. Plywood bending fixture.

Photo B. Hardware cloth mesh attached to ribs.

of the dish. Note that these sections may be cut alternately up and down from 24" hardware cloth to minimize material usage. The sections were cut wide enough to overlap at the ribs and attached with #6 sheet metal screws and fender washers. No peripheral stiffening is necessary because the finished edge is sufficient support. This method of applying the mesh also avoids many cuts and scratches. Photo B shows the rib assembly with the mesh applied to the ribs.

The Feed System

In choosing a feed system for this dish, I was confused by the complexity of the "feed horn" approach and could not visualize how both 2.4 GHz and 1269 MHz could function in the same enclosure. The adjustment looked tricky, and having the extra coax required for matching at 2.4 GHz bothered me. Having built several helix antennas, I thought that two concentric helices might be possible. It certainly would simplify aiming, compared to mounting two separate feeds off-center but on the same backplate. In fact, because Mode S aiming is so critical, skewing the receive antenna to compensate for off-center mounting would move the 70 cm antenna completely out of alignment. The concentric approach seemed the only way to go. Boy, did that raise some questions!

Would two helices mounted concentrically interact? With the 2.4 GHz helix being very close to a second harmonic of the 1269 helix, would it pick up enough RF to destroy the 2.4 GHz GaAsFET preamp when Mode L was being used? (I have nearly 50 watts in that Mode and it would be within 3/4" of the

smaller helix.) Since I planned to run my coax and power wiring through the support pipe for the feed, would that interact with the feed system? These were questions that I could not find answers for. I could only try the system for real answers and, happily, all were favorable. No doubt I will be challenged from some corner, but the proof is that the system works.

The performance of this antenna system exceeded my most optimistic expectations. I am able to clearly hear Mode S signals that were down in the noise before, and my own signal on Mode L is much stronger than it was when I used a pair of 13-turn helix antennas. The finished dish, in place, is shown in

Photo C. The construction of the feed is quite simple, as shown in the step-by-step photos. Photo D is the 7" diameter backplate with the coax fittings in place. Two 9/16" holes, appropriately located on the periphery of the helix coils, were drilled to mount Type N connectors, and two other holes were drilled to secure the center tubing. The large hole was cut with a hole saw in a drill press; the others, simply drilled. The coax fittings were mounted with 4-40 bolts into tapped

holes. The tubing support holes were tapped for 6-32 hardware.

The center support tubing is a 6" long, 1-1/2" diameter PVC tailpiece standard plumbing fitting cut to 3-1/2" long, leaving the flange for securement. I coated the flanged end with PVC cement, inserted it in the 1-1/2" hole and secured it in place with two 6-32 bolts and washers.

The 2.4 GHz helix is three turns of #14 wire wound as a left-hand thread on the center support. I secured the lower end by carefully soldering it to the innermost type N fitting, wound it with 1" spacing between turns, and secured it at the outer end by bending it inward through a small hole drilled for that purpose. Photo E shows the helix mounted to the tubing. A small piece of brass shim stock is soldered to the coil near the backplate for impedance matching. A 3/4" PVC pipe thread to cement joint adapter is inserted in the support tubing. There is a stop in this fitting to keep the unthreaded pipe from entering the adapter too far. I removed this stop with a 1" drill and then cemented the adapter in the outer end of the 1-1/2" tubing, threaded end out. This is the support for the entire feed system. You now have a 2.4 GHz helix feed!

The 1269 MHz helix consists of two turns of 1/4" copper tubing. I wound this also as a left-hand thread, three inches inside diameter, spaced 2" between turns. One end was drilled to slip over the pin of the coax fitting and then the coil was carefully soldered in place. I used a piece of Lucite 1-1/2" i.d. and 3" o.d. to support the outer end of the 1269 helix. After drilling a small hole in the Lucite, I tied it with several turns of plastic fishing line.

Photo C. Completed dish in place on the rotating bar.

Photo D. Coax fittings in place.

Most Revolutionary High-Frequency Amateur Radio Antennas in 20 years!

The FLYTECRAFT™ SFX Line of Monoband Vertical HF Antennas

Fig. Prod

• 5 unique models for 40, 30, 20, 15, 10 meters. Each only 9 ft. tall (10 meter is slightly shorter) • Precision internal wound helix gives full-size, incredible performance - world-wide DX or domestic. • Praise from everywhere: ENGLAND - "Your vertical sounds great!" CZECH - "I can't believe your antenna is only 3 meters high!" • Instant set-up and tear down, or leave up permanently - unobtrusive; ideal for antenna-restricted areas. Separates down to 4 ft. • Antennas boast low angle radiation. • Easiest-To-Use antenna made! Uses 2 shortened radials with RADIALCOILS™ - stretch them out or coil them up. (10M uses 3)

Committee asked the Digital Committee to look into the issue. A meeting was held between the Digital Committee and representatives of the HF packet community in late September 1992.

(11.) A meeting of the IARU Region 2 General Assembly (held in Curacao, Netherlands Antilles) just before the September 26th meeting between the Digital Committee and HF packet enthusiasts produced another—substantially revised—HF band plan—including segments for automatically controlled data communications.

(12.) The new IARU band plan provides segments on each amateur HF band for digital modes including RTTY, AMTOR, packet—defined as including new systems such as Clover and Pactor—but excluding facsimile and SSTV. CW would continue to be permitted throughout all amateur bands.

(13.) The League now recommends that:

(a.) Amateur stations may be operated under automatic control using any accepted protocol for data transmissions within certain small frequency segments;

(b.) Such stations should be equipped with a means to limit transmissions to no more than five minutes in the event of an equipment malfunction or interruption of contact with another station;

(c.) Third party communications may be transmitted under automatic control, using any authorized emission mode [Baudot, AMTOR, ASCII] provided that the retransmitted messages originate at a station that is being locally or remotely controlled;

(d.) HF data operation should be permitted outside those specified subbands only under local control;

(e.) The rule which prohibits automatic control while transmitting third party traffic (except packet stations using the AX.25 protocol on the 6 meter and shorter wavelength bands) should be changed so as to permit RTTY and other modes under automatic control on HF frequencies as well as at VHF and above.

The ARRL recommends the following new Part 97 wording:

Section 97.109 Station Control.

(d.) When a station is being automatically controlled, the control operator need not be at the control point. Only stations transmitting RTTY or data emissions, and stations specifically designated elsewhere in this Part, may be automatically controlled. Automatic control must cease upon modification by an EIC (Engineer-In-Charge) that the station is transmitting improperly or causing harmful interference to other stations. Automatic Control must not be resumed without prior approval of the EIC. RTTY and data stations operating under automatic control on frequencies below 50 MHz must use a digital code permitted in 97.309(a) [Baudot, AMTOR or ASCII] of these Rules, and must

incorporate provisions for discontinuing transmitter operation in the event of malfunction, or interruption of communications with another station.

(1.) Stations transmitting RTTY or data may be operated under automatic control in the 6 meter and shorter wavelength bands: 28.120-28.189 MHz; 24.925-24.930 MHz; 21.090-21.100 MHz; 18.105-18.110 MHz; 14.094-14.0995 MHz; 14.1005-14.112 MHz; 10.140-10.150 MHz; 7.100-7.105 MHz; or 3.620-3.635 MHz.

(2.) Stations authorized by these rules to transmit RTTY or data communications under automatic control may transmit third party communications. Any retransmitted messages on behalf of any third party must originate at a station that is under local or remote control. *TNX W5YI Report, Vol. 15, Issue #4, February 15, 1993.*

Newcomers Grow by Another 5% in 1992 . . . Versus a 54% Increase in 1991

The final licensing statistics are in! Nearly 75% of all first-time ham operators chose the Code-Free Technician path into amateur radio during 1992. The Novice class continues to decline with 38% less beginners choosing this route than a year ago.

The number of beginners leaped by 53.8% in 1991 due to the establishment of no-code hamming. In 1992, there was a slight increase: 4.0% (44,748 vs. 42,660). *TNX W5YI Report, Vol. 15, Issue #4, February 15, 1993.*

Canadian No-Code

The Basic No-Code ham ticket came to Canada in late 1990. It was responsible for a 5.3% growth rate that year and another 10% in 1991. 1992's figures show an increase of 20% over 1991 through the third quarter! There are now about 35,000 ham licensees in Canada. (By comparison, there are 90,000 licensed hams in California alone!) Amateur license fees in Canada were also increased to \$23 this year. *TNX W5YI Report, Vol. 15, Issue #3, February 1, 1993.*

Want A Dish?

Continued from page 32

The two helices should be tuned for minimum VSWR on their respective frequencies. This is done by bending the small brass strips closer to, or further from, the backplate, measuring as you go. The finished two frequency helix feed and the brass impedance matching strips are shown in Photo F. I am fortunate in having a Bird wattmeter and slug for the 1269 MHz frequency for this purpose. I had no equipment to adjust the 2.4 GHz helix. However, since this is a receive only frequency on OSCAR 13, it is not as critical as the 1269 adjustment.

I did not include any kind of isolation of the 2.4 GHz (SSB UEK 13) converter to protect it from the 1269 MHz RF. This was a gamble that I took after discussing it with

Gerald Rodski, SSB's US representative. Jerry thought that this unit was tuned tightly enough to exclude the 1269 RF. While I was able to get by without protection for the Mode S converter, a more conservative approach would isolate it from the Mode L helix by a suitable RF relay.

I am grateful to Bob Douglas W5GEL for his encouragement and counsel on my project and to Keith Berglund WB5ZDP, whom I have never met, for his excellent mechanical design. Other data was gathered from the *RSGB VHF/UHF Manual*, the *ARRL Handbook*, and heaven knows how many other references. I hope that this concept may encourage others.

Note: A kit of formed, and drilled parts ready for assembly is available for both the dish and the feed from *Majara Corporation*, 408 Liberty Rd., Sturgis MI 49091; (616) 651-6394.

The Wideband SUPERCONE ANTENNA
TX/RX, 10 meter, VHF, UHF and Microwave bands

SUPERCONE™

WE APOLOGIZE
Due to the tremendous sales of the Supercone we have had to pull our ads to avoid customer dissatisfaction with long deliveries. NOW THAT STOCK EXISTS FOR IMMEDIATE DELIVERY WE ARE BACK WITH THE ORIGINAL SUPERCONE AND SUPERCONE PLUS AT A REDUCED PRICE \$89.99 FOR ORIGINAL SUPERCONE

- ARRL approved, 73 review in April 1989 and *Monitoring Times* review in August 1989
- Ideal for indoor/outdoor use
- Use either standing on radials or 50' in the air
- Only 2 lbs., rugged construction, no hollow tubing, US made, 5 minutes to assemble
- Expandable to TX/RX on all HF bands (Supercone Plus) no added radials needed, ideal for all transceivers, scanners
- Full money back guarantee

The SUPERCONE PLUS
TX/RX, HF, VHF, UHF and Microwave bands

The j•Com Zetel SDP-600 Smart Patch

Most hams, at some point in their development, dream of having an autopatch. In the old days, before there was a repeater on every hilltop, hams saved up their money to put an autopatch on the local repeater. Nowadays, hams dream of having a patch on their base at home so they *won't* have to use the local repeater. At any rate, the convenience of being able to make a call from the car, or even the drama of being able to phone in an auto accident, provide the material for a great many ham daydreams.

As with most daydreams, things go pretty well until the first "reality check." In this case, the balloon pops at the point where the hero reaches for his checkbook. Autopatches aren't cheap. The basic home-brew variety is cheap enough—but you need your own repeater to use one. Any patch smart enough to be used with a simplex base station has a big enough price tag to scare off the most imaginative daydreamers—until now.

The j•Com Zetel SDP-600 Personal Autopatch may not answer all of your dreams, but it will certainly take care of your autopatch problems—at a reasonable price. The key word here is "Personal." The SDP-600 is designed for the basic needs of the home user. It provides all of the basic autopatch functions, plus the intelligence to perform simplex sampling, for just under two hundred dollars. In addition, a few "frosting on the cake" features are thrown in as well.

Autopatch Operation

In order to understand the operation of the SDP-600, it may help to review basic autopatch operation. As an example, an electronic phone patch has to perform the exact same functions as that stateside ham running phone patches on 20 meters for those servicemen overseas. First, the ham must establish contact with the ham on the other end. She then takes the phone off hook and dials the number. Once the situation is explained to the stateside callee, the conversation begins. During the conversation, the stateside ham must perform VOX (voice operated relay) functions. In other words, she must wait until one party is done talking, and then switch her transceiver into the other mode until the other person finishes speaking, etc., etc., etc. (On

"non-auto" patches, the parties on both end of the conversation will agree on a key word that lets the ham know when she should flip the switch. You know, something like "I love you, honey. OVER.") Once the conversation is over, she needs to hang up the phone. If she's a good operator, she'll even ID her station.

Those are the bare minimum functions required to perform a phone patch, whether on 20 meters or 2 meters. Operation of an automatic phone patch is very similar. Consider the Personal Autopatch installed on a simplex base station at our own home. Once we are within range of our house, we take the phone

In an ideal world, this type of simplex autopatch would work pretty well. In reality, some modifications to the system need to be made since we're connecting a simplex system (the radios) to a duplex system (the telephone). Simplex autopatches usually fall into two categories. The main problem to be circumvented is that of dealing with a simplex mobile and base—two radios that can't talk and listen at the same time. One way to get around this problem is called "sampling." A sampling autopatch puts the base station into transmit at the same time the phone comes off hook, transmitting the phone line audio to the mobile user. In order to tell if the mobile

The j•Com Zetel SDP-600 Smart Patch.

off the hook by dialing an access code, and the "*" sign. The SDP-600 responds with a short burst of dial tone. We dial our number, followed by another "*" The SDP-600 gives us a confirmation beep, and REDIALS the number on the telephone line. When the called party answers, their voice triggers the VOX circuit in the Autopatch, and keys up the base transmitter until they stop talking. The mobile can then key his transmitter, which allows him to talk to the called party. This VOX operation keeps up until the conversation is finished. At this point, the mobile operator dials a "#," which hangs up the phone, completing the call.

ever transmits, the patch simply "samples" the receive channel by momentarily changing from transmit to receive. This sample might occur for a quarter of a second, and repeat every two seconds or so. If the base hears the mobile during the sampling period—by detecting carrier, subaudible tone, or audio, depending on the system—it discontinues the transmit/sample mode and goes into receive. It will stay in receive, passing the mobile audio down the phone line, until the mobile's carrier drops. The base will then go back into transmit/sample, and the landline audio will be transmitted to the mobile. This is an effective system, and it keeps the mobile operator firm-

ly in control of the base station, since he can transmit a turn-off code at any sample interval—a couple of seconds at most. Unfortunately, the sampling cuts “holes” in the landline audio, making it difficult to understand under marginal conditions. In addition, the rapid transmit-receive transitions of sampling systems are best suited for newer radios without relays—and radios that don’t mind the heavier duty cycle.

The second type of simplex system is called “cross lockout VOX.” This system uses VOX circuits to key the base transmitter, based on the landline caller’s audio, and to keep the base in receive when the mobile is transmitting. As long as either party continues speaking, they will have control of the system—the other party can’t interrupt (he is effectively “locked out”). The VOX system provides for a more natural flow of conversation, and makes for more readable copy under marginal conditions. Its main drawback comes from the fact that the mobile operator has to wait until the landline caller has finished speaking before he can interrupt or send commands to disconnect the patch. This has interesting social and legal implications. As an example, this means that if your pal launches off on the five minute story of how he caught that big bass last week, forgetting that he told you the same story this morning, there isn’t a thing you can do about it until the five minute story is over. Likewise, if the person you’re talking to notices a pot boiling over on the stove and rushes off, putting the phone down next to the stereo speaker with that Andrew Dice Clay album on—well, we’re in trouble here. More likely is the problem of the mobile operator getting used to the need for the base carrier to drop before he tries to send commands to the autopatch. This means that if you transmit your phone number while the base is sending you dial tone (no big deal—I do this on the telephone all the time) the base won’t hear the DTMF tones, and you’ll get a wrong number. Once you do get the wrong number, it will probably be one of those almost endless recordings from the phone company which will keep the VOX keyed for a full minute, only dropping for a millisecond just as you’re going through heavy traffic.

As in life, the best answer is usually a compromise. The folks at jCom have produced a VOX autopatch with an intermittent sampling feature. It works as a normal VOX system, except that it samples right after the landline caller takes control of the VOX, and every 20 seconds thereafter. Each sample is preceded by a beep tone to let you know that it’s coming. In other words, you get the smooth flow of a VOX system, plus the ability to jump in and wrench control of your base station away from your foul-mouthed friends. What could be simpler?

Well, as long as you asked, duplex. In a duplex system, where both the transmitter and receiver are active in both the mobile and

the base, the mobile can send tones any time he needs to. People can interrupt and be heard. In those cases where you might not have a duplex mobile, the mode is known as half-duplex. The repeater is still duplex, and transmits the landline audio as long as the patch takes the phone off hook. The simplex mobile still pushes to talk, and listens when he’s not talking. (If you’ve made a phone patch on the local repeater using your HT, you’ve made a half-duplex patch.) With the proliferation of dual-band mobiles and bases around, personal full-duplex autopatches are becoming very realistic. This would give you the same feel as an actual cellular phone conversation—but due to the Rules and Regs, you just couldn’t talk about anything interesting or important! In any case, the SDP-600 can handle all of these modes—the limiting factor is your radio.

Extra Functions

In addition to these basic features that make for a workable phone patch, the SDP-600 has a few more functions that make life easier. DTMF tones from the mobile are received, decoded, and re-generated before be-

“If you’re looking for a well-built, full-featured basic autopatch for home or repeater use, at a price that won’t break the bank, the jCom Zetel SDP-600 could be just the ticket.”

ing passed to the phone line, in order to ensure noise-free tones at the central office. An access code of up to four digits can be used to prevent unauthorized use of the patch. A second access code can be set to allow general use of the patch, but to restrict toll calls to authorized operators. (If you’re the trusting type, these codes can be programmed out—that is, the unit will work the same as our basic patch described above.) A reverse patch function allows the patch to pick up the line when the phone rings, and send a ring tone out to the mobile. A CW ID function lets the user program in his callsign, which will then be transmitted at the beginning and end of each conversation. Timeout features are incorporated as well. If you drive out of range of your base station, the Personal Autopatch will disconnect after 30 seconds of no activity. A feature with a lot of potential is the “control output.” This is simply an open collector transistor that is brought out to the rear connector. It’s activated with an Access Code + “1” command from the mobile. This output can be hooked up to a relay, which can then control anything you desire. You might want to use it to enable or disable another radio at the site, or to reset that troublesome TNC. Less serious types will want to turn on the yard light before they pull into the driveway, or turn on the coffee maker when they’re five miles from home.

Hook up and installation of the Personal Au-

topatch is very straightforward. It’s designed to use the mike connector levels of the average rig—mike level audio out, and speaker level audio in. (This means there’s no need to dig through the radio to find detector audio.) Ground and PTT are also needed. There are four potentiometers in the unit to adjust in the event of unusual phone or radio levels, but these are pre-set at the factory for average levels. (The review unit worked fine right out of the box, even considering the lousy phone system here in the New Hampshire boon-docks.) The hardest part of the whole installation will be soldering the four-conductor interconnect cable without burning your fingers.

Wish List

The only drawbacks I found with the SDP-600 were of the “wish list” variety, not actual problems. For instance, the LEDs on the front panel indicate radio audio, phone line audio, power, and three status points, labeled S1, S2, and S3. These three status LEDs change configuration as the patch performs various functions, but it’s difficult to intuit what the various combinations mean. Examples are given in the manual, but a series of more meaningful indicators (OFF-HOOK, ACCESS CODE RECEIVED, PROGRAMMING MODE) would be very helpful, especially during installation and troubleshooting. There is no battery backup in the unit, so any parameter programming is lost in the event of a power failure. The unit does revert to a usable set of parameters, including the firmware-based main access code, but a small back-up battery or a non-volatile memory arrangement would be a nice feature. (I know, I know—I want Cadillac features at a Chevy price—but it doesn’t hurt to ask!) [Ed. Note: Beginning March 1, 1993, jCom will be shipping units which include a non-volatile memory. In the event of a power failure or when not using the unit for long periods of time, these units will retain the codes entered. Customers who purchased the original units should contact jCom if they wish to have the upgrade added to their existing units. The cost of upgrading has not been determined at this time, but is expected to be under \$40. No change in the price of the phone patch is expected.]

In the event of a problem that the manual can’t answer, the technicians at jCom are both competent and friendly. My question concerning receiver carrier detect was answered quite promptly. If worse comes to worse, the unit is covered by a 90-day parts and labor guarantee, and a 30-day money-back-if-not-satisfied guarantee.

The jCom Personal Autopatch doesn’t do two-tone paging, doesn’t have a voice mailbox system, and won’t do multiple RF link control. It also doesn’t cost two thousand bucks. If you’re looking for a well-built, full-featured basic autopatch for home or repeater use, at a price that won’t break the bank, the jCom Zetel SDP-600 could be just the ticket.

UPDATES

Active Antenna Using a MOSFET

Refer to the above article on page 32 of the March 1993 issue. While the parts placement diagram is correct, we printed the PC board pattern in reverse. The correct PC board pattern is shown in Figure 1.

Quiet Down Your Shack, Part 1

Answers to the survey that first appeared in this column a few months ago continue to come in, but one thing is already clear: Two answers top the list of problems encountered by hams. The first one—and the subject of this column—is RFI (Radio Frequency Interference) caused by all the computerized equipment that we put in our shacks today. For help with the second most common reply, "not enough money to buy gear," see "Never Say Die" in this and previous issues of 73.

How Many Transmitters?

When you count the transmitters in your shack, do you stop at the radios? Well, even if they are not supposed to, computers and their associated peripherals can put out a pretty good signal. Sometimes there is nothing you can do about the interference. Usually, a few simple techniques will greatly reduce—if not eliminate—the noise.

Before we try to get rid of it, let's take a look at where the noise comes from. Microprocessors are used in just about all consumer electronics today. They control your VCR, clock radio, microwave oven, and even some telephones. Microprocessors are sequential devices—they perform one very simple step after another. They are driven along the way by a "clock." The job of the clock is to regulate the stepping of the processor. This clock is usually a crystal oscillator, a lot like the circuit used in a rockbound rig. One difference, though, is the output waveform. While in radio design we strive for a clean sine-wave output from an oscillator, processor clock circuits are designed for square-wave output. This is a requirement; you can think of each clock pulse as the throwing of a switch. The processor and its support circuitry want nice, snappy switch throwing with definite "on" and "off" states. The sine wave just doesn't fit the bill.

From the RFI point of view, only a sawtooth wave could be a worse choice. The square wave has lots of harmonics. This means that not only does a square-wave generator produce a signal at the intended frequency, but at odd multiples of it as well. These signals can be big. For example, the third harmonic of a square wave is about a third of the power of the fundamental frequency. The fifth is .200, the seventh .143, and it goes on like that. This may not sound like a lot of power, but remember two things: The first is the inverse square

law. This says that the signal strength from any source decreases at a rate equal to the square of the distance you are from it. Your computers are in your shack—pretty close, huh?

As computers have become more advanced, their clock rates have gone up. While five years ago a fast machine had a clock rate of 10 MHz, today's fast machine runs at 50. I know from your survey responses that many of you are running 33 MHz machines in your shack. On the other hand, it is often an older machine that is pressed into amateur service. These machines, with their slower clocks, can be a real annoyance to the HF aficionado. The clocks in these machines range from about 4 to 8 MHz, with 6 MHz very common, thanks to the original IBM AT design. You can see that the harmonic products of these machines fall in various places in the HF bands. The oscilla-

"No machine is completely quiet, and they all have certain peak output frequencies, but the receiver will tell you if the noisy spots are where you need quiet."

tors in computers are always run at twice the desired clock rate and then divided by two. This means that a 6 MHz machine has a 12 MHz oscillator.

Other devices that use microprocessors can often be more troublesome than the computer itself. This is because these devices use slower clocks—1 or 2 MHz—which make even more noise at HF frequencies. VHF and UHF users are not immune to this problem, though. For example, when I first purchased my Heath HK-21 "Pocket Packet" TNC, the oscillator in it put out a full quieting signal into the handheld to which it was connected at the incredibly inconvenient frequency of 145.010 MHz. You will recognize this as the primary packet frequency for the US.

What to Do?

Now that you have some idea of the principal culprit in this situation, let's take a look at some steps to clear it up. Keep in mind that your first defense is good station practice. Sometimes the only solution is to buy better equipment of one sort or another, but according to the survey results, this isn't a solution for many of you.

Pay the Price

The FCC has requirements that cover microcomputers and their garbage that they generate. If you

have a machine that you purchased for home use, it must be certified under part 15 regulations for radio emissions. This will be the case if you purchase an IBM, Packard Bell, Gateway 2000, Apple . . . you get the idea. This may not be the case (probably isn't) if you purchase a clone machine from a local builder. Even though these machines should be certified, they are most often not. This doesn't mean that all local clone shops build noisy machines. The lack of certification is usually due to the lack of financial resources—lots of money!—needed to get certification. The upshot is this: If you are looking to buy a machine, consider paying more for a machine you know will be quiet. If you plan on buying from a clone dealer, spring for the better case—this will provide better shielding. Bring a portable receiver with you (one that operates where you plan to) and check the machine out. No machine is completely quiet, and they all have certain peak output frequencies, but the receiver will tell you if the noisy spots are where you need quiet.

Another place that paying extra

Ground That Station!

Okay, everyone with a good station ground raise your hand. What, YOU don't have a good ground? There are lots of reasons to get a good RF ground in your shack. What is a good ground? Well first, a good ground is NOT the third pin on your electrical outlet. A good RF ground must be a low inductance path at the frequency of interest. Just because a ground connection has DC continuity doesn't mean you have a good ground for your radios. A bad ground can be worse than none, since it will work as an antenna rather than a path for unwanted energy.

So what is a good RF ground? You will hear many opinions on grounding practice, but here are the basics. First, you must have a good earth ground to use. This can be accomplished with three eight-foot ground rods about three feet apart. This may seem like a lot of work, and it can be, but it will insure a low inductance connection to the earth. If you can't do this—because of bedrock, cost, or 'cause you're lazy—get as close as possible. A single four-footer is better than nothing at all. Radio Shack carries decent ground rods in both lengths. Once you have a place to connect, you need to make the connection with the shortest possible piece of cable that will provide a low inductance path.

OK, let's step back for a second. That is the third time I mentioned "low inductance." What does this mean? Inductance is a kind of "electromagnetic inertia." It is the property of an electronic component (in our case a piece of cable) that opposes changes in current. Instead of the current flowing through the component, it is stored in a magnetic field around the component. The inductance of a component is related to the frequency of the energy trying to pass through it. A single wire will have a relatively high inductance at any frequency we are interested in, which is why we use a cable.

The particular type of cable usually used for ground connections is known as "bonding cable." It looks like a heavy-duty version of the shield from a piece of RG-8U coaxial cable. This cable is composed of many smaller conductors woven together. This provides the low inductance connection we want. You can usually find a spool of bonding cable at a reasonable price by searching the tables at hamfests. If you must purchase it from a normal supplier, make sure your wallet is full—this stuff isn't cheap.

Keep It Short!

The longer the distance to the grounding rods, the less effective your ground will be. Ideally, you should locate your shack either in the basement or on the first floor, where the trip to the ground rods is short. This is not always practical, though. Those of you who must run your

buys something is in the cables that run from the computer to its peripherals. Cheaper cables often have poor shielding, which makes them into radiators of all sorts of junk. Though we have been discussing the microprocessor's clock, there are others on the peripheral controllers that connect to those cables, just waiting to QRM your favorite frequency.

What is Shielding?

We all know about shielded cable and that it is resistant to interference, but how does it work? The principle behind shielding is the same as for a Faraday cage, named for British scientist Michael Faraday (1791-1867), who discovered that if he constructed a cage of conductive material and grounded it—in England they "earth" it—there would be no electromagnetic fields inside the cage. Today, classic Faraday cages made of copper screen are used in applications like EMP (Electro-Magnetic Pulse)-proof rooms, laboratories with instruments sensitive to EMF, and the like.

In the case of cables, computers, and radios, the shielded jackets and cases keep out the noise. But, note the requirement to *ground* the Faraday cage. The cage works by providing a low inductance path to ground. Radio signals striking the cage are basically "sucked" into the ground so they can't get past the screen (another British term).

Using and Stabilizing Varactor Diodes

Have you tried to buy an air variable capacitor for a receiver project recently? They are very rare these days. I've seen them advertised in British electronics catalogs, and in antique radio supplies catalogs in the USA, but otherwise it's catch as catch can. So, what to do? Well, it seems that commercial radio manufacturers today use voltage variable capacitance diodes, commonly called varactors, for the tuning function. These special semiconductor diodes exhibit a capacitance across the PN junction that is a function of the reverse bias potential (see Figure 1).

The diode representations shown in Figures 1a and 1b are in the form of PN junction diode block diagrams. In the N-type region negative charge carriers (electrons) predominate, while in the P-type region positive charge carriers (holes) predominate. When a reverse bias potential is applied, as in Figure 1a, the charge carriers are pulled away from the junction region to form a depletion zone that is depleted of charge carriers (hence acts like an insulator or "dielectric"). The situation is the same as in a charged capacitor: an insulator

separating two electrically conductive regions. Thus, a capacitance is formed across the junction that is a function of the width of the depletion zone. And because the size of the depletion zone is a function of applied voltage (compare Figures 1a and 1b), the capacitance of the junction is also a function of applied voltage. A varactor is a diode in which this function is enhanced and stabilized.

Figures 2a and 2b show two common circuit symbols for a varactor diode. In both cases, the normal diode "arrow" symbol is somehow combined with a pair of parallel lines representing a capacitor. In some cases, I've seen a variant on Figure 2a in which an arrow is drawn through the parallel plates by extending one side of the arrow symbol. I suppose that's used to indicate the property of "variableness."

Several different varactors are listed in Table 1. Several of these are also easily available in the ECG and NTE replacement transistor lines sold by parts houses that normally deal with radio-TV repair shops. Look up the specs for NTE-611 to NTE-618, or ECG-611 to ECG-618 to see if they are appropriate for your application. Alternatively, look up the replacements for those diodes in the table from the ECG or NTE crossover directories.

Varactor Tuning Circuits

The varactor diode wants to see a voltage that is proportional to the desired capacitance. Several different circuits are used to provide this function, some of which are shown in Figures 3 and 4. In all cases, the tuning voltage must be supplied from a reference voltage source that is very stable. It is normally considered good engineering practice to provide +Vref from a separate voltage regulator that serves only the varactor, even when the maximum value of the voltage is the same as the rest of the circuit (e.g. +12 volts). Therefore, always use a voltage regulator to provide the tuning voltage source potential. Most varactors use a maximum voltage around +30 to +40 volts, while many intended for car radio applications are rated only to +12 or +18 volts (check!).

The simplest and probably most popular circuit is shown in Figure 3a. In

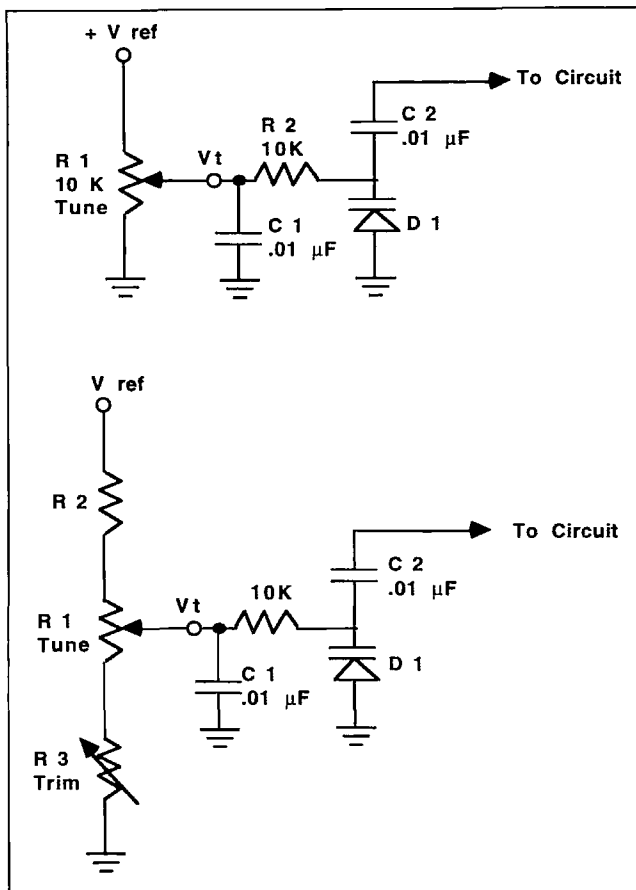

Figure 3. Varactor diode tuning voltage circuits.

this circuit, a potentiometer (R1) is connected across the Vref supply, so the tuning voltage (Vt) is a function of the potentiometer wiper position. In many cases, a 0.001 μ F to 0.01 μ F capacitor is connected from the wiper of the potentiometer to ground in order to snuff any noise pulses so they don't alter the tuning (they are, as far as the diode is concerned, valid tuning voltage signals!). A series current-limiting resistor (R1), usually of a value between 4.7k ohms and 100k ohms, is used to protect the diode in case the voltage gets to the breakdown point, and also to isolate its capacitance from the tuning circuit (otherwise, C1 would always predominate). In many cases, a DC blocking capacitor (C2) is needed to prevent the tuning voltage from affecting following circuits, or other circuit voltages from affecting the varactor diode tuning voltage. From the point in Figure 3a marked "To Circuit," the varactor network acts like a variable capacitor.

A variant circuit is shown in Figure 3b. In this circuit the tuning voltage is only a small portion of the reference voltage. Thus, the tuning voltage is produced by a voltage divider made up of three resistors: R1, R2 and R3. In

some cases, one or more of the other resistors will be a trimmer potentiometer to set the "fine" or "vernier" frequency of the overall circuit.

Regardless of which tuning circuit is used, the resistors, including the potentiometer, should be low temperature coefficient types in order to reduce thermal drift. Ordinary carbon composition resistors are probably not suitable for most applications.

If you wish to sweep a band of frequencies, i.e. in a sweep generator or swept receiver (e.g. panadapter or spectrum analyzer), then replace the +Vref potential with a sawtooth waveform. The sawtooth waveform is a linear ramp that rises to a specified maximum voltage, and then drops back to zero abruptly. Unfortunately, it is rarely the case that the sawtooth voltage range, the desired swept fre-

PACKET & COMPUTERS

Continued from page 40

ground connection from the second floor might try using copper water pipe, which will have lower inductance than any wire and be cheaper than bonding cable. By the way, copper pipe makes an excellent substitute for ground rods if you have some lying around.

So you've got your good earth connection, and you've got your short run to your shack, now what? The next component that you need is a ground buss. The ideal grounding buss is a flat piece of copper with copper screws for connection to it. The point of the ground buss is to accomplish what is called a "star ground." In this scheme, all ground connections are made to a single grounding point which is itself connected to the earth. DO NOT "daisy chain" the ground connections from one piece of equipment to another. This just provides a path for ground loops and other signal messiness. The star ground is clean because the path of least resistance for RF and offensive signals is to the earth and NOT to other equipment. The reason we use copper is for low resistance. It is traditional and probably best; however, if you must use something else because of cost or availability, it will still work.

Now you've got a place to connect all of your equipment to ground. Your radios will have a ground screw, no problem there, but what about the computers? Most computers expect to be grounded through the three-pin AC connection, but as I said before, this is probably not a good ground for RF. Next month we'll take a look at grounding the computer equipment, and other steps you can take to reduce RFI in your shack. In the meantime, put in the grounding system. Not only will you get advantages when you ground your RFI-generating equipment, you'll also see great improvements in the performance of your radios with the new ground.

How to Contact Me

In addition to the address at the top of the column, you can use one of these electronic addresses to write to me:

jsloman@bix.com

This address is good for anything: questions, answers, business or fun.

N1EWO@N0ARY.#NOCAL.CA.U.S.A.NA

This address is for fun only; no business, please.

I look forward to hearing from you about this column or any other topic of interest. Please let me know what you would like to read about, and any other comments that you have. 73 de N1EWO

Q : Always Stuck In Reverse?

A : You won't be with DAIWA Cross Needle Meters!

World famous Daiwa Cross-Needle Meters eliminate the major headache of using your antenna tuner: the constant recalibration of your VSWR meter - and throwing the FWD/REV switch back and forth as you change bands, modes and power levels. With Cross-Needle metering, you get hassle-free, full time power, reflected power and VSWR readings simultaneously at a glance.

From the originator of the Cross Needle meter, Daiwa offers models to suit every application, band and power level . . .

- CN410 series-compact mobile HF and VHF/UHF models (2 power levels) with custom backlit meter for easy & safe night viewing.
- CN101 series-for PEP and average power reading base station use with models for HF and VHF/UHF.
- Deluxe NS660 series-with models covering 1.8MHz thru 2.5GHz, all power levels, PEP or average reading with exclusive multiband remote sensor capability.
- Hi-Tech DP800 series-for computerized, fully automatic digital PEP or average power reading in three models for 1.8 thru 525MHz.

The Original Daiwa Cross Needle Meters. Often imitated but never duplicated! Once you start using one you'll wonder how you ever got along without it!

...because knowledge is power!

A Packet Radio Program for the Macintosh®

- Written specifically for Macintosh® (not a port from DOS)
- System 7 compatible, 32 bit clean
- Implements the full Mac user interface, including:
 - Scroll bars in session windows (view previous traffic)
 - Edit menu with Undo, Cut, Copy and Paste commands
 - Saving and Printing of all or part of any session window
 - User re-sizeable split windows
- Supports multiple simultaneous connections each in its own window
- Change "channels" quickly by simply switching windows
- Simultaneous transmission and reception of packets in every session window
- Icons and fields in each window display that session's status
 - Packets outstanding and sent, retries, round trip time
- Stations Heard window displays the last 20 stations heard, and continuously updates the list while the window is open
- Monitor window decodes and shows all packet traffic
- Acts as a fully functional digipeater including the ability to assign an alias
- Operates with any TNC that implements KISS mode
- Fully compatible with Aaron Wohl's SoftKiss and Sigma Design Associates' PacketMac Modem

CARR'S CORNER

Continued from page 42

quency range, and the varactor voltage characteristic are in sync with each other. For those situations we need to be able to provide a sawtooth of variable amplitude to set the sweep width and a DC offset tuning voltage to provide the center frequency function. Figure 4 shows how this might be done.

The circuit shown in Figure 4 uses three operational amplifiers to provide the combination tuning voltage. Op amp A1 provides a variable amplitude sweep width control to change the sawtooth amplitude. If feedback resistor R5 is made 10k ohms, then the output sawtooth will have the same amplitude as the input sawtooth. If higher or lower amplitude is needed, then adjust the gain of A1 by selecting a different R5 value: Gain = $-R5/R6 = -R5/10k$ ohms (the "-" indicates that the circuit is an inverter). For tuning voltages to 18 volts, ordinary 741s can be used for A1 through A3.

Digital frequency control can be accomplished by supplying the reference voltage (+Vref) from a digital-to-analog converter (DAC) that has a voltage output. The binary number applied to the DAC binary inputs will set the tuning voltage, which in turn sets the capacitance of the diode. Those who wish to experiment with low cost components will find that the eight-bit National DAC0800 series devices (available in most local parts stores in the Jameco Jim-Pak display) will provide 256 different steps of voltage (hence also of capacitance and frequency). An op amp is recommended to convert the current output of the DAC080x to a voltage (the national Linear Data Book gives example circuits as well as specs for the different devices in the series).

Temperature Compensation

There is one nasty little problem with the varactor tuning circuit—the thermal drift can be horrible! According to one source, the temperature coefficient of capacitance (ppm/°C) varied from about 30 ppm/°C at +Vref = 30 volts to 587 ppm/°C at +Vref = 1 volt. Ouch! There are three approaches to this problem: ignore it; use Figure 5 or Figure 6.

The circuit shown in Figure 5 uses a fixed, regulated voltage for +Vref,

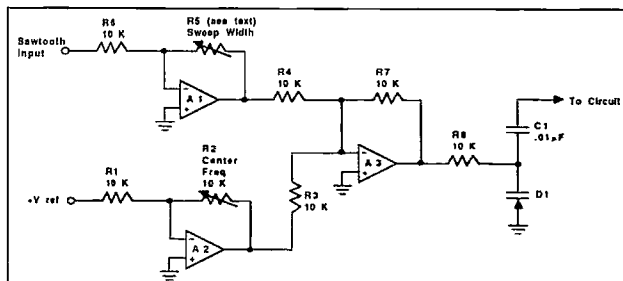

Figure 4. Sawtooth/center frequency combiner circuit.

Figure 5. Simple diode thermal compensation circuit.

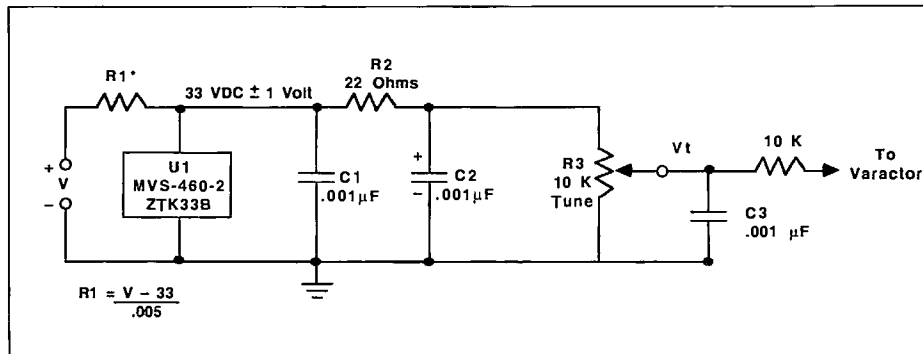

Figure 6. Using a special varactor thermal regulator IC device.

but passes it through an ordinary silicon diode (D2) that is in close thermal proximity to the varactor diode (so they see the same temperature environment). When resistor R1 is set to draw a current through D2 sufficient to get the voltage drop into the 0.6 volt region, then the output voltage

appears to be a +33 volt zener diode that has a -2.3 mV/°C temperature coefficient. It will provide a nominal +33 volt output for all input voltages (V) greater than 34 VDC. Again, the temperature stabilizer (which looks like a diode) is placed in close thermal proximity to the varactor diode

"Digital frequency control can be accomplished by supplying the reference voltage (+Vref) from a digital-to-analog converter (DAC) that has a voltage output."

+Vref will track the thermal changes to counteract the change of capacitance. In practice, R1 can be the tuning potentiometer when diodes such as 1N4148 or 1N914 are used.

Figure 6 shows a circuit using a special zener diode voltage regulator sold in Europe under both MVS-460-2 and ZTK33B type numbers. It ap-

pears to be a +33 volt zener diode that has a -2.3 mV/°C temperature coefficient. It will provide a nominal +33 volt output for all input voltages (V) greater than 34 VDC. Again, the temperature stabilizer (which looks like a diode) is placed in close thermal proximity to the varactor diode

being protected. The MVS-460-2 part is in a TO-92-like plastic package, while the ZTK33B is in the normal glass diode package (similar to 1N60 devices). Unfortunately, the MVS-460-2 and ZTK33B are hard to find in the USA. I bought some from Maplins Professional Supplies in England (P.O. Box 777, Rayleigh, Essex, SS6 8LU, England) for £0.382 each (as of this writing £1 = \$1.57, but the rate changes daily so check before sending money orders denominated in pounds sterling) in lots of 25 or more. Unfortunately, with a minimum practical order

of several pounds sterling, plus a shipping charge of £8 for USA and Canada, it is best to order 25 or so. This translates to \$27.38 or so, if the price still holds as of publication date. Ordering from the UK is reasonably easy. You can get an international money order denominated in pounds sterling at many banks, but the fee might make you puke (my bank gets \$15, which is why I opened a UK checking account). Alternatively, they will accept Visa, MasterCard or American Express cards. The bank card company will make the currency conversion for you, and they use the rate in effect on the day they make the conversion. I've used all three types of cards to make purchases from UK electronic and old book dealers (my other passion), and have experienced no problems. Give them the card number, expiration date and your signature authorizing the charge.

Well, that's that for varactors. If you want to know more theoretical smoke about the subject, then I recommend Motorola Semiconductor's application note AN847 "Tuning Diode Design Techniques" (Motorola Technical Literature Distribution Center, POB 20912, Phoenix, AZ 85036).

The Two-Fer

Mr. Webster describes a "classic" as being excellent; established; a standard; a model of its kind. This month we'll take a break from the charge controller to work on a simple spring classic: the Two-Fer. Yes, it was around for a while and it's been through several changes since its conception in the *QRP Quarterly*. The original Two-Fer came from Mike Michaels W3TS and John Collins KN1H. I had my hand in the first prototype PC boards and produced the first Two-Fer kits for Dayton. The kits sold out in a matter of minutes.

Several different versions have appeared in many articles. This is a modification of a modification, so to speak. Bryon Weaver WU2J did the modifying this time around. He changed out the FET used for the VXO and instead installed a common transistor. Notice that the output transistor has also been changed from the 2N3553 to an MRF476. This is a 5 watt RF transistor in the flat pak style.

The circuit will produce 2 watts out on 14 MHz with 13 volts VCC.

New Keying Circuit

This time I changed the keying circuit around. Connecting the jumper to either the "A" or "B" connection on the PC board will determine how the oscillator will be keyed.

With the original Two-Fer, the oscillator ran all the time. The oscillator supplied the matching direct conversion receiver with the needed injection for the balanced mixer. The matching receiver for the Two-Fer was a real dog. Most builders of the Two-Fer simply did not build the receiver. Therefore, you had to remove the VCC from the crystal oscillator so you could hear the other station. Otherwise, the crystal's frequency would be heard in your receiver.

With this version of the Two-Fer, you can select how you want to run the crystal oscillator: continuous or keyed. The output of the VXO may be coupled to a direct conversion receiver by a small-value capacitor. Unless you are planning on using the oscillator to drive a direct conversion receiver mixer (as in the original version),

then use the keyed oscillator configuration. This way you won't have to do any fancy VCC switching when going from transmit to receive.

A capacitor for coupling RF to a receiver mixer may be mounted on the PC board. If you don't plan on using this feature you may leave the capacitor out. But, by installing it, you have a handy place to pick up the output from the VXO. I use a frequency counter for that digital readout feeling everyone is so used to.

"QRP" column to mute the receiver and control the antenna relay if you wish. The choice is up to you.

Construction is quick and easy with the PC board from FAR circuits. Of course, you could use just about any other method to build the circuit, including perf-board. The so called "ugly" construction would work fine, too.

Notice the use of a ferrite bead on the base lead of the transistor. This improves stability in the PA under certain conditions. In some models, I had

"Construction is quick and easy with the PC board from FAR circuits. Of course, you could use just about any other method to build the circuit, including perf-board."

If you have a sluggish crystal and keying the oscillator causes chirp, then simply configure the oscillator to run continuously. Of course, you'll need to remove the VCC during receive, but you won't be chirping CW anymore either!

Solid-State QSK

This version also has something new: a solid-state QSK system. By adding a small handful of parts we end up with a no-relay QSK. Best of all, you don't have to include this feature if you don't want to! You can use the T/R controller shown in an earlier

no problem with the PA stages running away without the bead; using other transistors required installing the bead. In either case, mount the transistor as close to the board as possible.

Most of the parts can be picked up from your local Radio Shack. You should be able to build this transmitter for less than \$20, even if you buy all the parts new. If you have a well-stuffed junk box, your total cost may be next to nothing. A junk box CB would be a good source for the final PA transistor and driver. In fact, I've used several different types of transis-

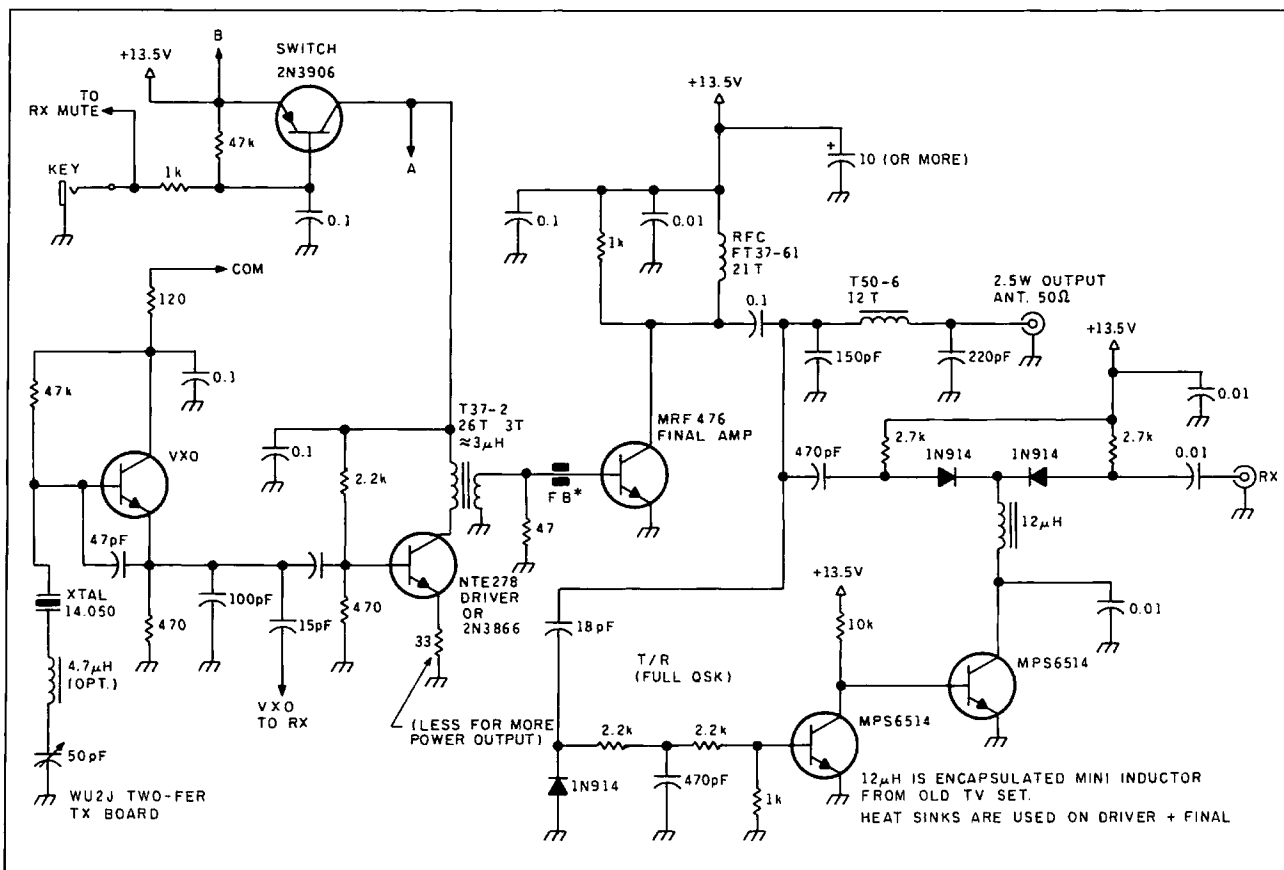

Figure 1. Schematic.

The values for the output filter are for the 20 meter band. I put one of

Figure 2. PC board and parts placement.

these rigs on my favorite band, 30 meters, by changing the output filter. I did not change the driver transformer at all. The rig works just fine on 30 meters as well as on the 20 meter band. I did not use the QSK feature as I use my T/R controller instead. I see no reason why one could not put this rig on any other band, with the exception of 10 meters, by changing the

Even though this is simple project, some of the parts may be hard to come by. KA7QJY Components at P.O. Box 3893, Logan UT 84323 has everything you need to get this rig up and running. Send him a large SASE for his part price lists. Of course, a PC board for the project is available from FAR Circuits, 18N640 Field Court.

Next month we'll get back to our charge controller project and put those power MOSFETs to work.

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

While the possibilities of a packet digipeater in orbit tempts the imagination with standard 1200 bps AFSK on FM with the yet-to-be-launched Arsene satellite, other satellite enthusiasts are enjoying great high-speed, 9600 bps packet operation via KITSAT-OSCAR-23.

The satellite was launched on August 10, 1992, representing the product of a cooperative effort between the Korean Advanced Institute of Technology (KAIST) and the University of Surrey in England. Jeff Ward GØ/K8KA acted as Project Manager for the effort. After launch from the French Guiana Space Complex with the TOPEX/POSEIDON scientific satellite and the French S80/T communications experiment, KO-23 spent five months in engineering check-out. Many earth pictures were taken by the excellent dual-camera system and other experiments were exercised. It has even been programmed to "speak" via the 70 cm downlink.

KO-23 was released for general digital communications access on January 15th. Opening messages in several languages were posted to the satellite bulletin board system (BBS) by the Korean control station HLØENJ. Within days, stations around the world were uploading messages, software and picture files. The data transfer capability of this digital amateur radio satellite is greater than any other. Signals are strong and correctly modulated from the transmitter, while the receivers are quite sensitive. The 1300-km-high orbit provides longer access than the UoSAT and microsat series. These factors have made KO-23 the choice for digital satellite fans.

Within a week the request queue was loaded with callsigns on every pass over the United States. Activity is also high in Europe and other densely populated areas. Users quickly discovered the utility of KO-23's digital system and its ease of

use and time in the sky, compared to UoSAT-OSCAR-22 with its lower orbit and slightly higher Bit Error Rate (BER) caused by its transmitter.

Earth Station Equipment

To get active via KO-23 several items are needed: a 2 meter FM transmitter for the uplink, a 70 cm FM receiver with preamp for the downlink, antennas, a terminal-node controller (TNC) with a 9600 bps modem and a PC-compatible computer running special software to communicate with digital amateur radio satellites.

While most stations employ circularly-polarized beam antennas for KO-23 work, some have had reasonable results with omnidirectional antennas such as J-Poles or Lindenblads. Better results come with better antennas, but experimentation can yield surprising outcomes. Steve WB5TTS has been quite successful from deep South Texas with omnidirectional antennas mounted on his truck parked outside his apartment. Any pass over 20 to 25 degrees elevation yields good downlink copy and uplink access.

KO-23 has two uplink frequencies, 145.850 and 145.900 MHz. A simple FM transmit system with 25 to 100 watts Effective Radiated Power (ERP) works well to get into the satellite. Since the transmitter must be operated at 9600 bps, the input microphone amplifier must be bypassed. Simple inexpensive FM transceivers can make good high-speed uplink rigs once the internal drive point (usually at the varactor diode) is found.

For reception of the 70 cm downlink on 435.175 MHz, a scanner or 70 cm FM transceiver with a good GaAsFET preamp and a small beam will do very well. To get digital data from the receiver, the signal must be brought out from the discriminator circuit prior to the audio amplifier stage. In many of today's radios the discriminator circuit employs only one IC, an MC3357 (or similar). Pin 9 is the discriminator output and can be connected

Photo C. Congratulations to KAIST and HLØENJ uploaded to the KO-23 BBS by JH1AOY in picture (.GIF) form.

via a shielded cable to the "audio" input of a high-speed 9600 bps modem.

The easiest way to get going on 9600 bps is to check the TNC manufacturers for high-speed TNCs or TNCs that easily connect to existing high-speed modems. PacComm in Florida has been marketing satellite modems and high-speed TNCs for a number of years. They can be reached at (813) 874-2980. For those interested in some construction work, the Tucson Amateur Packet Radio Corporation (TAPR) has released an updated version of their TNC-2 compatible 9600 bps modem kit. TAPR's phone number is (602) 749-9479. New options include the Digital Signal Processing (DSP) units from L. L. Grace [(609) 751-9705] and Advanced Electronic Applications, Inc. [(800) 432-8873]. When looking for a 9600 bps solution, ask the TNC or modem manufacturer for information concerning connections to your radios. Some are very simple to interface, while others may not even be worth the effort.

The current group of digital amateur radio satellites all use a communication protocol system that differs from that used in terrestrial AX.25 packet networks. Fuji-OSCAR-20 is the only excep-

tion. F-O-20 work requires a Phase Shift Keyed (PSK) modem hooked to a standard TNC, while the others need additional software running in a PC connected to the TNC along with specialized modems.

The satellites employ a broadcast protocol that does not require a connected state to exist between the earth station and the satellite. A user sends a file request to the satellite for a file seen in the directory. The satellite starts the transmission of the file from space. Other stations may also request certain files or pieces of files. The satellite gives each station five seconds of downlink per rotation in the queue. The queue holds a maximum of 20 callsigns. While this may not seem like much, many times a station wants more than one file. While waiting to get all of one, the station may hear and collect pieces of other needed files. When finally requesting the other file, it may already be 90 percent complete, thus requiring very little time to finish. The broadcast protocol has some flaws but works much better than separate connections for each user. It is not uncommon to collect over 500 kb of files in a single pass.

Photo A. KITSAT-A Project Manager Jeff Ward GØ/K8KA and Toshio Tango JR8XPV in the UoSAT control center at the University of Surrey in England. (Photo by JR8XPV.)

Photo B. Photo of the KITSAT team at the Korean Advanced Institute of Technology uploaded from Korea and downloaded from KO-23 by WB5UUK.

Photo D. Many pictures are uploaded to the KO-23 BBS for worldwide distribution. At 9600 bps transfer can be very fast, even with the shared downlink.

Photo E. Pictures, graphs, drawings and even test patterns can be found in the KO-23 BBS.

The user software is called PB.EXE. The current version was released on April 30, 1992. When running, the program takes control of the communication activity. After setting a few parameters like call sign (KO-23 is HL01-11 for PB) and file grab preference (you may not want to collect everything) the program makes file requests and updates the directory of active satellite files when the satellite is in view. In only a few days many megabytes of disk storage can be filled with E-mail,

images and new software packages from all over. The PB.EXE software is available free on many terrestrial BBS systems. The AMSAT-DRIG (Dallas Remote Imaging Group) BBS is accessible at (214) 394-7438. The software is also provided with *The PACSAT Beginner's Guide* from AMSAT [(301) 589-6062]. AMSAT does not ship the disk separately, but the manual with disk is an inexpensive \$12 in the U.S.

More information on 9600 bps

modems can be found in the December 1991 "Hamsats" column. Other details concerning the high-speed digital satellites are in the October 1991, July 1992 and November 1992 columns.

Since UoSAT-OSCAR-14 began open operation for 9600 bps packet, many changes and advances have taken place. Today, much terrestrial packet mail is sent via satellite. This has caused congestion but has provided a service to the amateur community. With many experi-

ments still to be run on KO-23, and the possibility of a new Katsat in orbit as early as September, concern has been voiced about spreading the satellite gateways to the new hamsat. For now, it's all KAIST experiments and individual packet operation. More 9600 bps satellites are on the way. They work extremely well. In a few years we can expect 56 kbps satellites and compressed digital video, but for now a few megabytes a day via KO-23 will have to do.

The ears have it!

“The R8 is like a breath of fresh air, with its ground-up engineering and up-to-date digital control from the front panel. I am very pleased to see a quality HF receiver of American manufacture that should successfully compete on the world market.”

Bill Clarke
73 *Amateur Radio Today*

When we introduced the American-made R8 Worldband Communications Receiver, we knew it would be judged by some very discerning ears, experts accustomed to the finest in short-wave listening equipment from around the world. After listening to the world on the Drake R8 loud and clear, they have delivered a decisive verdict.

They appreciated the R8's sensitivity, clarity, simplicity, and all-around versatility so much that many of them declared the R8 simply the best of its class. High praise, indeed, from very well-traveled ears.

But why take the word of mere

experts? Put the Drake R8 to the test yourself with a 15-day money-back trial period on factory direct purchases, and let your ears be the judge. If you're not impressed by Drake's quality, performance and ease of operation, all in a receiver costing less than \$1,000.00, return the R8

Receiver within 15 days, and we'll refund your money in full, less our original shipping charge. To order your R8 factory direct, for more information, or for the dealer nearest you, call **1-800-723-4639** today. We're confident that once you've listened to the R8, your ears will hear of nothing else.

Radio Direction Finding

Joe Moell, P.E., K00V
P.O. Box 2508
Fullerton CA 92633

Computerized Triangulation, Part 2

Ask a group of radio direction finding (RDF) enthusiasts why they enjoy mobile hidden transmitter hunts (sometimes called foxhunts or T-hunts), and you'll get many different answers. These events are social, educational, challenging, exciting, mysterious, and fun. While some think of a T-hunt as an opportunity to joy ride with radios, I prefer to take my time, be methodical, and savor the experience.

However, there are times when haste is mandatory. During hunts for repeater jammers or stations in distress, all mobiles must work together. One operator becomes the search coordinator, gathering bearings from each station and triangulating them to predict the location of the emitter.

Last month's "Homing In" showed how a computer can speed up cooperative T-hunts. You saw how Fast-Workspace, a Macintosh Excel spreadsheet macro program developed by Paul Terlund WB3JZV, triangulates bearings from as many as 20 hunters at once. It calculates up to 190 fixes and determines a refined position estimate in less than a minute using a double-averaging algorithm.

Where's My Balloon?

As a member of Edge of Space Sciences (EOSS), Paul wanted Fast-Workspace to do more than just locate stationary targets. EOSS is a Denver-based non-profit group of hams who promote science and education through amateur radio and high-altitude balloon flights. EOSS launches helium balloons lifting high-tech scientific packages, including 2 meter tracking transmitters.

Successfully recovering 20 pounds of expensive electronics, dozens of hundreds of miles downwind, depends on the EOSS T-hunt team. After touchdown, the beacon's range might be very short due to its location. There is also the possibility that beacon transmitters may fail in flight or at impact. Thus, it's vital for hunters to track the package continuously throughout the flight.

EOSS has launched nine of its own balloons, plus one for another club. With WB3JZV's computer aiding in the search, the recovery rate so far has been one hundred percent.

Of course, the computer doesn't do it alone. A dedicated team of RDFers makes it happen. On the day before launch, Tom Isenberg N0KSR estimates the balloon's touchdown

point, using the latest data on wind direction and speed at various altitudes.

All hunters must use the same map and coordinate system for computerized triangulation. The standard map for EOSS is the Pierson Graphics Colorado State Recreational Map. Hunters put transparent overlays with a grid of 5-mile-by-5-mile squares on their maps. Point 0.0 on the grid (the origin) is selected by Tracking and Recovery Group Leader Greg Burnett K0ELM, based on the predicted landing point.

"We could use aeronautical maps and do the grid in degrees of latitude and longitude," says WB3JZV. "But aeronautical don't have good road markings for hunters on the ground. So we just superimpose our standard grid on the Pierson map and our X and Y coordinates tell us where we are and where the T is."

On Your Marks . . .

As last month's QRM-hunt example showed, triangulation errors increase when cooperating T-hunters are grouped to one side of the target. Field Coordinator Bob Ragain WB4ETT (Photo A) would prefer to have them spaced out around the predicted impact point, but the roads and terrain may make this impractical. Furthermore, the balloon sometimes moves horizontally faster than the mobiles can follow.

While guidance in positioning is given on EOSS flights, each team selects its locations based on its own judgement. Each is assigned a tactical callsign (Station Alpha, Station Bravo, and so forth) for ease of identification during the hectic recovery period.

Unless all stations take bearings on a fast-moving balloon at exactly the same time, the balloon's horizontal velocity will cause triangulation errors. So tracking stations stay in radio contact. The primary net is on the Colorado Repeater Association's 2 meter field repeater, placed at a high point near the predicted impact zone. When teams are out of this repeater's range, they can call on 2 meters to Jim White WD0E in Denver, or on 40 meter SSB via Dave Gilpin KB0LP.

Net Control gives a time mark whenever bearing information is needed, normally at 15-minute intervals. Hunters take bearings at these time marks and relay them via the repeater or base stations to WB3JZV. Standard message format consists of the team's callsign, tactical call, location X and Y coordinates in miles relative to the origin point, and bearing in de-

Photo A. EOSS Recovery Team members prepare carefully for each flight. George Riedmuller N0NJM (left), Bob Ragain WB4ETT and Dawn Ragain N0OCW are studying the standard map used by all RDF stations. (Photo by Ann Trudeau KA0ZFI.)

grees with respect to true north.

WB3JZV's FastWorkspace program creates separate spreadsheets for each sample time. Basic data, including launch time, launch point coordinates, callsigns, and tactical calls, is entered only once. As bearings come in for each sample, Paul types all the hunters' location coordinates and bearings next to their callsigns on the Calculations spreadsheet (Figure 1), then mouse-clicks the Triangulate button. Excel calculates the balloon location and displays it and the surviving fixes on an X-Y chart (Figure 2).

The balloon's location and predicted path is announced on the tracking net so mobile stations can reposition themselves as appropriate.

With another mouse-click, Paul activates the Save-and-Revert macro. It puts the prediction from this sample time into the Results spreadsheet and calculates balloon velocity and heading based on location change since the last sample. Excel then automatically saves the Calculations spreadsheet for this sample to disk and creates a new Calculations spreadsheet with operators' names and calls list- ed, ready for the next sample.

All distances and standard deviation units are statute miles.
SD_X is the standard deviation over all x-coordinates.
SD_Y is the standard deviation over all y-coordinates.
SD_Dist is the standard deviation over all distances from initial location estimate (aka Figure of Merit).
9:45 and 10:00 estimates were the worst with SD_Dist of 79 and 128 miles respectively.

Figure 3. Excel adds a line to the Results chart after each sample and estimates the balloon's speed and heading. Mobile T-hunters use this data as they attempt to follow the balloon's path.

Figure 4. The scatter chart of data in the Results spreadsheet shows the balloon's complete flight path.

A Typical Flight

EOSS flight #9 lifted off from Longmont, Colorado, at 0930 MST last October 31. The payload dangling from the 70-foot balloon included a telemetry and command module with two 2 meter tracking beacons. There was also a video system with a black-and-white camera and a 1-watt ATV transmitter. A commandable gimbaled mirror gave the camera views of the ground, the horizon, and the balloon above.

Balloons for scientific flights will eventually break and drop the payload, which parachutes to earth. But the time and altitude at which breakage occurs is very difficult to predict and control. On an EOSS flight in May 1992, the payload unexpectedly stayed in the air for almost 18 hours and ended up in Nebraska, almost 220 miles from the launching point! One goal for this flight was controlled separation of the payload from the balloon, and the package included a device to release the payload on command.

Fourteen T-hunters provided bearings from their mobiles or base stations at one time or another during the flight. The greatest number of bearings triangulated at any one time was 12 at 10:45 a.m., when the bal-

"WB3JZV uses the Station Performance Sheet and practice runs to help searchers take better bearings. 'Before the balloon goes up, I put on a little accuracy check exercise for those stations that care to partake,' he says."

loon reached its maximum altitude of 92,000 feet. The payload drop mechanism worked perfectly, and the package began its descent.

Figures 1 and 2 show the calculations spreadsheet and scatter chart for the last set of bearings, taken just before loss of signal as the package neared touchdown. The triangulated location at that time was only four miles from the eventual pickup point.

The RESULTS.FINAL spreadsheet (Figure 3) and scatter chart (Figure 4) clearly show the balloon's path from Longmont to the grasslands near the town of Briggsdale. Erroneous predictions at 9:45 and 10 a.m. occurred because most hunters were clustered in the predicted touchdown area, 60 miles northeast of the rising balloon.

The Station Performance Sheet (Figure 5) summarizes how each RDF team performed, as judged by the number of times that the program rejected fixes based on that station's

Station Performance Sheet													
Call Sign	Name	Number of Rejected Points at each Sample Time										Total Triangula Pts

Figure 5. The program computes this summary of RDF accuracies after the flight. Stations with bold call signs were fixed, while the remainder were mobile.

bearings. Rejections occur because bearing pairs are parallel or divergent, or when a fix is too far away from the main cluster of fixes at that sample time.

The lower the rejection rate, the better. It is unlikely that any station will ever achieve zero rejections, especially when hunters congregate on one side of the target,

as they do early in the flight.

Sharpshooters' Secrets

WB3JZV uses the Station Performance Sheet and practice runs to help searchers take better bearings. "Before the balloon goes up, I put on a little accuracy check exercise for those stations that care to partake," he says. "I go somewhere within the

footprint of the field repeater, fairly close to it. Everybody picks their RDFing spot, then calls in and gives their bearing to me and their grid location. I plug the data into the computer and tell them what their bearing error is."

"I've questioned a couple of guys who get real bull's-eyes, less than a degree of error," Paul continues.

"They are consistently red-hot hunters. Before they sight down their antenna booms toward the signal, they take compass bearings on a distant terrain feature from various spots within a 30-foot radius. Then if they're in a local magnetic disturbance, they can tell it and move as necessary. When taking bearings, they take several readings from nearby locations to average out multipath."

I tried out WB3JZV's programs and they worked just fine. I used them to generate the examples in last month's column. If you would like to experiment with computerized triangulation, they are available for your non-commercial use.

For a 3.5" Macintosh disk with macros and spreadsheet files, send \$10 to Paul Ternlund, 15459 East Saratoga Place, Aurora CO 80015. Specify standard or high density disk type. As usual, neither 73 Amateur Radio Today nor I can guarantee this offer. You will also need Microsoft Excel version 3.0 or higher to run the macros.

Congratulations to Paul and the rest of the EOSS crew for developing educational and enriching uses of amateur radio. For more information on EOSS, contact Vice President Marty Griffin WA0GEH, 1647 East Geddes Circle North, Littleton CO 80122.

Enjoy NEVER CLIMBING YOUR TOWER AGAIN

Are you too scared or too old to climb? Never climb again with this tower and elevator tram system. Voyager towers are 13 and 16 inch triangular structures stackable to any height: in 7 1/2', 8 3/4' or 10' section lengths. Easy to install hinge base, walk up erection. Next climb tower with leveling bolts in base. Mount rotor and large heavy beams on Hazer tram and with one hand winch to top of tower for normal operating position. Safety lock system operates while raising or lowering. At last a cheap, convenient and safe way to install and maintain your beam. This is a deluxe tower system that you can enjoy today.

SPECIAL TOWER PACKAGE: 50 ft. high by 18" face tower kit, concrete footing section, hinged base, HAZER kit, Phillystran guy wires, turnbuckles, earth screw anchors, 10' mast, thrust bearing, tool kit, ground rod and clamp, rated at 15 sq. ft. antenna load @ 100 MPH. **\$1974.95.**

HAZER KITS
HAZER 2 for Rohm 25-nv duty alum 12 sq ft wind load **\$324.95**
HAZER 3 for Rohm 25-stud alum 8 sq ft wind load **\$232.95**
HAZER 4 for Rohm 25-nv galv stl 16 sq ft wind load **\$303.95**

Keep On Walkin'

Last month, we were discussing walkies. Let's take up where we left off.

If your walkie is getting power, something should be happening. If the radio is still completely dead, it is very likely that no power is getting to the circuitry. Once you've eliminated bad connections, the power switch, fuses and such, the next place to look is the voltage regulator. Depending on the rig's design, there may be more than one. Especially if you get no computer operation (no display or response to keypresses), check that power is getting to the micro. If not, trace it back until you find it. Although today's walkies use CMOS micros, most of which don't require regulated voltage, many still use regulators, more for the purpose of isolating the micro from possible voltage spikes or reversed polarity than anything else. A dead regulator will, of course, shut down the micro, and it may cause the rig to look totally dead when it really isn't.

If the rig does turn on, but doesn't

The Tech Answer Man

work properly, you must troubleshoot it like you would any radio. Before you do, though, it pays to give some thought to the specific problems walkies encounter.

QRM

Many hams use their walkies as mobile rigs. Some even use them as base stations. Suddenly, they are complaining that their receivers don't work properly. For some reason, they can't hear the local repeater. Everyone else can, so something must be wrong with the walkie, right?

Not necessarily. The front ends in walkies are rather small, and there usually isn't room for much in the way of bandpass filtering. Also, nearly all new rigs have very wideband receiving capabilities, making filtering impractical. The result is that, when connected to an outdoor antenna, the average walkie is swamped with out-of-band signals, overloading and desensitizing the front end. Remember, walkies are designed for use with those little rubber dummy loads they come with, so the front ends are optimized for sensitivity, not resistance to overload.

By the way, an exception to this "rule" is the Radio Shack HTX-202,

which does not have extended-coverage receive. Instead, there's lots of bandpass filtering, making that radio pretty immune to signals which will wipe out other sets. Despite the rumors going around on packet radio, there are no modifications to enable extended receive on this rig; the hardware just won't support it. Oh well, there's a price to pay for everything, right?

If you encounter a receiver desense problem, the first thing to do is switch to the rubber duck antenna and see if it goes away. I remember having such a problem in Miami once. Using a quarter-wave mobile whip on the roof of the car, I could get into the repeater just fine, but I couldn't hear it very well. I switched to the duck and, even inside the car, I could hear it just fine. The problem is even worse with big base station antennas; there's just too much signal strength. These problems do not indicate any malfunction of the radio, and you shouldn't go in and adjust anything. You just have to accept the limitations of such a small radio.

Speaking of antenna issues, I've seen many instances of worn or broken BNC connectors causing trouble. Especially if you connect various antennas and cables, it can wear out. If your receiver sensitivity suddenly drops way down or becomes intermittent, take a good look at that BNC. If the center receptacle is obviously worn, you may need a new jack. If it

looks OK but the problem persists, check the connection to the PC board. In some rigs, wobbling of the connector can crack the connection. Also, sometimes the BNC can simply be loose. If it is, you can bet your ground connection is no good. With most rubber ducks, it doesn't matter because they don't use the ground anyway. But, when you go and hook up a mobile antenna, it doesn't work properly. The fix is simple: a good, solid connection through a tightly secured BNC.

Hello? Hello?

Another common walkie problem is a blown speaker. If you use the rig in the car, you probably have to turn it all the way up, or nearly so, in order to hear it. Some rigs which put out 250 to 500 milliwatts of audio have speakers which are only rated for 100 milliwatts! Under normal conditions, it's no problem. But, when you blast it all the way up for a while, that poor little speaker's voice coil may fry. If the rig works via the earphone but the speaker is silent, disconnect one wire from the speaker and check the voice coil with an ohmmeter. It should either be OK or be open. If it's open, you need a new speaker.

A long time ago, I had an odd experience with this problem. I bought a used walkie which apparently had had a blown speaker. The previous owner had replaced it with a generic one. The

radio worked, but it always seemed off frequency on receive! Oddly, when I pulled it apart, it worked fine. As soon as I put the two halves of the case together, it got distorted again. After scratching my head for a long time, I noticed that the back of the speaker was very close to the discriminator coil. And, the replacement speaker had no shielding behind its magnet. You guessed it—the magnetic field was detuning the discriminator. I got a new speaker from the manufacturer and the problem went away. In today's micro-mini world, you pretty much have to get most parts from the radio's maker. Otherwise, you risk winding up with a kludge that doesn't work quite right.

Lookin' Bad

Today's walkies use LCDs to show your operating frequency and other parameters. I've covered LCD problems in previous columns, but I'll go over the basics again here. Unless the rig has been dropped and the LCD is obviously broken, most likely a display problem is caused by bad contact between the PC board and the display. If the radio works properly but all or part of the display is missing, chances are that water, cigarette smoke or another contaminant has worked its way into your rig. Most LCDs are connected via conductive rubber strips pressed between the display's edge and contacts on the board. It takes good, clean contact and

reasonable pressure for it to work. For that reason, the LCD is mounted such that it is pressed pretty hard against the board. Sometimes, the radio's case is used as a housing, with the board being screwed up against the display. Other times, there's a frame for the LCD, and the whole thing comes out of the case as a unit, because the frame is mounted to the board. The frame approach seems to work better, but either scheme can allow junk to get inside and mess up the display. To clean it, you must separate the display from the board, clean the edge of the display, the conductive rubber and the board, and then put the whole thing back together again. I've successfully used isopropyl alcohol. Just be very careful not to drip any on the rig's plastic case or display window, because many plastics are permanently damaged by contact with alcohol. The conductive rubber strips don't seem to have any problem with it, though.

Getting Pushy

Keypads also can get gummed up. If you must disassemble one for cleaning, be extra careful when you pull it apart. Many rigs have individual buttons which are not joined together, and it is very easy to lose them. Always remove the PC board with the radio's face pointing down, in order to keep the buttons in place. Even if you don't lose any, they often get turned around

or out of order, so take a look from the front before you screw it all back together again. I can't count the times I've forgotten to do that and then had to take it all back apart immediately after reassembly. Arrgh.

Go To It

Other than these walkie-specific issues, HTs are no different than any other radios, and normal circuit problems must be troubleshooted in the usual way. So, get out that scope and go to it! Now, let's look at a few letters:

Dear Kaboom,

I know this is kind of a weird question, but I'm hoping you can help. One of our lovely California earthquakes has caused a broken circuit to the ceiling heater in our bedroom. I have no idea where the break is. Any idea how to find it?

Signed,
Brrrr

Dear Brrrr,

Yes, this is an odd question, but I believe ham radio can come to the rescue! You're a ham, so why not use some RF? First, be *absolutely sure* that all power is disconnected from that grid of wires. I'd disconnect your main circuit breakers to be sure. (Just for safety, double-check with a voltmeter.) When you know there's no power there, try a little QRP! What I'm suggesting is that you make a battery-

powered, very-low-power transmitter. A milliwatt will do. Then, connect it to the wire feeding the heating grid. Now, take a small radio and move it along the ceiling until you find the signal. You should be able to find the break pretty easily; the signal will drop way off. If that doesn't work, you could try a little more RF power (maybe a watt) and a field-strength meter. Either way, I'd use a fairly low frequency, perhaps 80 meters, so that you don't mistake nodes in the wave for the broken wire. Good luck!

Dear Kaboom,

I've started building a 15 meter QRP rig and discovered that I've used carbon film resistors instead of the carbon composition resistors called for. Should I replace them with carbon composition parts? Is this substitution likely to affect the performance of my rig?

Signed,
EI Switcheroo

Dear EI,

Yes, it will affect performance—the rig may work better! Seriously, though, carbon film resistors are more expensive and made to tighter tolerances than carbon composition units. As far as I know, the film resistors are no more inductive than the comp ones, so it should work fine. Good luck with your rig!

73 and see you all next month.

HAM HELP

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. You may also upload a listing as E-mail to Sysop to the 73 BBS, (603) 924-9343, (8 data bits, 0 parity, 1 stop bit, 2400 baud), on Special Events Message Area #11. Specifically mention that your message is for the Ham Help column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

We want to exchange our vintage communication receiver, Radio Holland Type BC348W valve-type, frequency coverage 200 KHz to 18,000 KHz (in 6 bands). Receives AM, CW, and SSB and is in perfect working condition. Would like to trade for any QRP SSB amateur band transceiver with at least 20 meters, but would like all the bands. Must be in working order. We also want to exchange a Drake TRM-24 100 watt Marine band (2, 4, & 8 MHz) SSB transceiver. Has no VFO but has 11 preset crystal channels. Will trade for amateur band QRO or QRP transceiver. Does anyone have information on converting the Drake to the amateur bands, have a schematic diagram, and/or have the address of the Drake Company? Address: Arshad H. Quadri (AP2AHQ), Larkana Amateur & SW Listeners

Club, No. 1989/A 1 Shaikh Street, Karma Bagh Larkana 77150, (Sindh) Pakistan. Thank you in advance.

Wanted: Manual and schematics for EICO 722 VFO. I will pay copy and shipping charges. Gary Trudel VE3MPQ, Windsor Ontario, Canada. Tel. (519) 944-2962.

Wanted: All About Cubical Quads by William Orr, which is now out of print. Will pay. Thanks. Rob Adham KB8KEA, 603 McKee Rd., Beaufort SC 29903. Tel. (803) 521-4554.

Needed: Schematic for Heathkit Signal Tracer IT-12 and Hallicrafters Receiver S-107, and voltage charts. Bill Mollenhauer N2FZ, 136 Cedar Ave., Pitman NJ 08071.

NEVER SAY DIE

Continued from page 4

businesses. But I know that almost everyone listening is going to continue a life of quiet desperation, nailed down to a lousy job somewhere, lighting rush-hour traffic twice a day.

Sure, I wish that hams would read my book (\$13 postpaid from Uncle Wayne's Bookshelf), subscribe to my *What To Do* newsletter (\$10 for ten issues), and get excited about changing their lousy state and our lousy federal government. A few have read it. And a few of those are talking about action and forming groups.

When I ask for a show of hands at my talks . . . how many of you have worked over 300 countries? Maybe one hand goes up. I ask who's been active on OSCAR. Another hand goes up. How about RTTY? Two hands. How about 75 meter DXing? No hands. How about 2m sideband? Two hands. How about 6 meters? No hands. How about moonbounce? No hands. Packet? A couple dozen hands. SSTV? No hands. ATV? One hand. 10 GHz? No one. Hidden transmitter hunts? Couple hands. MARS? Three hands. Contests? Four or five hands. I'm wondering if Uncle Wayne's Bookshelf should stock enema bags.

None of this cost a lot of money. Most of my life I haven't had much money. I still don't, in my own mind. But a lack of money has never stopped me from doing different things

in amateur radio. It costs peanuts to whip together a pair of microwave transceivers and head for the mountains. I remember Howie W2QHH, who had around two-and-a-half zillion certificates collected. He ran maybe 100 watts to a dipole, and he had a ball.

I decided to have some fun one DX contest weekend and fired up my rig on 20m. I wanted to see if I could work 100 countries in one weekend on 20m. Well, I did it . . . just barely. My 100th was just seconds before the end of the contest. Will I ever forget the time I decided I'd work all 50 states on 75m. It took me three nights to do it, and that wasn't even during a contest. Three nights, all night.

My first DXpedition was to Navassa Island, back in 1958, and I'm still talking about it and showing pictures. I'll never forget a minute of that trip . . . boy, that was exciting! We came damned close to getting killed several times.

Well, I'll tell you what. Instead of having anything in mind to talk about at Dayton this year, I'll let you ask questions . . . if you have any. Otherwise I might start talking about things which will be of little interest to you, like some of the things I write about in my editorials . . . like how the mind/body works, or how to cure all illnesses, to lose weight, to fix our rotten educational system, to cut state and federal expenses, to get work, to make really big money, to cut crime by around 80% or more, to cut taxes sub-

stantially, to live longer, to get rid of welfare, and other non-ham matters which are probably of no interest whatever to someone who's driven all the way to Dayton for a super ham-fest. You want to scrounge the flea market and to see all the new ham gear on display, not get involved with politics or health things.

Heck, if you had any interest in living very long you wouldn't have that huge beer belly hanging out under your tee shirt, be smoking or drinking beer, right? There I go being a scold again . . . being mean. I really do appreciate the hundreds of you who've stopped by the 73 magazine booth to thank me for getting you to lose weight and stop smoking. I also enjoy it when someone tells me that it was my editorials that got them to go into business for themselves, giving them the first real freedom they've had since they were kids.

The 73 Booth

Speaking of the booth, we aren't going to have one this year. Now, I want to tell you that that was a tough decision, but we added up the outrageous cost of the booth space, of shipping the booth stuff out to Dayton (and back), and sending out three people to stand in the booth. Then we added up what we usually take in selling subscriptions and books. Whoa there, we've obviously got to stop booting at Dayton. It still makes economic sense at all the other hamfests we attend, but the sales at Dayton just

don't justify our buying a booth any longer.

A couple of our staffers will still be going, but instead of standing around in the booth for three days, they'll be going around the hamfest visiting the exhibitors to see what's new and to talk about advertising, new product reviews, and so on. If I can find a place to park anywhere near the arena I'll be wandering too, so say hello when you see me. Yes, of course I'll have some discount subscription forms with me. David Cassidy suggested I push around a shopping cart full of my books to sell. Not a bad idea. I could sort of live out of it like a bag lady since I won't have a booth to store the usual ton of stuff I can't stop myself from bringing along . . . HT, cameras, a few samples of my CDs, my laptop computer, and so on.

So I'll try one more year giving a talk and see if there seems like enough interest for me to bother next year. My talk is at 1 p.m. on Saturday, if you aren't too busy haggling over something in the flea market to bother. Maybe it'll rain again and help pack my room. I'll do a little rain dance.

Another CQ?

Sure enough, a *third* magazine with that title! There's the ham contest magazine, then *Congressional Quarterly*, and now *CQ (Communications Quarterly)*, published by Digitel. Being in the communications equipment business, I suspect they've never

Teaching Through Learning Channels

In almost every case, the success or failure of any course, amateur radio included, depends on the effectiveness of the person in front of the room. This is one reason why teachers are encouraged to keep going back for in-service courses and to continuously keep abreast of new educational techniques.

One of the best postgraduate courses I ever took was something called "Teaching Through Learning Channels." The goal of the class was to teach instructors how to observe the signals that students exhibit, indicating how they prefer to learn. These signals are the continuous reference points by which we, as teachers, recognize what it is that students need in order to learn.

I believe that these skills of observation are crucial to the development of good teachers and instructors. Being a skilled observer in the classroom can make the difference between being a good teacher and being a great one. Learning to observe and interpret

the kinesthetic/tactile, auditory and visual clues that students of all ages demonstrate in a class will enable the teacher to relate these clues to the students' learning styles.

A really professional teacher knows the value of being flexible in his or her teaching style. Teaching, as well as learning, should be an ongoing process. The instructor who has learned to expand his or her style to include concrete, abstract, sequential and global strategies will inevitably be the one whose students get the best of meaningful learning experiences.

I get many letters from teachers who want to know how to keep the motivation high with young people in a ham radio program. The answer is really the same as it would be for the successful teaching of any discipline: The teacher must continuously increase his or her knowledge, refine his skills, and expand his teaching resources.

Studies have shown that students learn best when a teacher teaches to the preferred learning channel of that person. A learning channel is a way or method by which an individual is able to best process information: visual, auditory, or kinesthetic. The teacher of amateur radio is fortunate enough to have the opportunity to be able to hit

Photo A. Concrete/sequential strategies include step-by-step directions to complete a task.

all these learning channels in creative and stimulating ways.

Let's define some of these techniques so that any teacher or instructor reading this can begin to incorporate a fresh approach into his own teaching style.

The Concrete/Sequential strategy includes doing such things as having field trips organized step by step, with a goal; structured demonstration lessons; simulations that follow the rules; using step-by-step directions to complete a task; and using concrete

materials and following directions. The ham radio instructor can plan field trips to local museums with ham radio stations or electronics exhibits; or plan a visit to the radio room of a major communications center in the area, such as police or fire radio and dispatch rooms; or plan a visit to a local ham who has an impressive station.

The Concrete/Global strategy involves giving choice-optional assignments involving real things, concrete problem-solving simulations, learning through trial and error and using real

objects, committee work on real projects, and discovery learning. There are hundreds of basic electronics experiments applicable to every age group which can be used in an exciting way in the classroom. If you have a large group, break them up into smaller units and provide materials for each group to work with and record their results.

The Abstract/Sequential strategy includes lectures, with questions and answers, in a step-by-step progression; audio and/or video tapes in a step-by-step sequence, almost all textbooks, explaining theories through deductive reasoning, getting the main idea through sequential presentation, and programmed instruction. The good teacher will choose the appropriate textbook, handout materials, etc. for the age and interest level of the group and use this as only one of the teaching strategies to be utilized in the classroom.

The Abstract/Global strategy is having open-ended think sessions, group discussions, allowing think time for reflection before beginning a project or assignment, optional reading assignments, and allowing the students to get their own "Aha." Having a student at the front board during the group discussions is a good idea. The student can make a list of the key words of the discussion. When the class gets divided into triads or small groups after the discussion, they can refer back to the key words and use them to plan their own next steps for their task.

Learning Channel Inventory

About one week into the new term, I administer the following inventory to my classes. The kids have fun filling it out, and I am able to use the results to plan my initial teaching strategies for that particular group.

Check four to six statements that identify how you prefer to learn.

When learning, I prefer to:

- Work with real things.
- Talk to myself while reading a book or questions on a test.
- Read material about what I'm learning.
- Sketch or doodle while learning.
- Hear things explained first.
- Watch a film or video.
- Work with materials related to what is to be learned.
- Listen to tapes, the radio or recordings.
- Watch someone illustrate or demonstrate the information.
- Perform through simulations, games, role plays.
- Listen to experts describe and explain the information.
- Look at charts, maps, graphs or pictures.

Plan your teaching strategies to match the results you get on your inventory. It's probably safe to say that the more you are able to correlate the two, the more effective your teaching will be. Be flexible, monitor your results, and be involved with the learning process of your students. Teaching

Photo B. Ham radio in the classroom lets you use a multimedia approach to learning. Shown here: An ATV demonstration.

amateur radio allows you to have a multimedia approach to learning. Take advantage of it!

Be sure to join us at the Dayton '93 Hamvention Youth Forum on April 24th. I'll be showcasing youngsters

from all across the country. We've got a dynamic, accomplished group of children who will be speaking this year. Please come and meet them and bring some children along with you. C U there.

Link Communications RLC-1 Repeater and Linking Controller

- (2) Full Featured, Full Duplex, Repeater/Link Ports
- Both ports can operate as Connected or Stand Alone Repeaters, Cross-Connected Link Ports, or Both
- Each Port has its own ID message, Courtesy Beep, Hang Timer, TOT Timer, ID Timer, and CW Frequency; All user Programmable
- Completely DTMF Programmable, No Factory ROM programming needed
- (4) Analog Lines Programmable for Temperature and Voltage Readings
- (4) Input Lines for Contact Closure Readings at your repeater site
- (5) Output Lines for control of external peripherals, and site functions
- Both ports have COR and PL inputs allowing off site access changes
- DTMF access from either port, with EPROM Variable Storage
- 2400 Baud Serial Port allows Computer, Packet and Modem programming
- All commands can be renamed from 1 to 4 digits in length
- Independent DTMF muting function can be assigned to each port
- Analog Lines have Voltage source for the LM335 Temperature Sensor
- Doug Hall: RBI-1 Remote Base Control of Kenwood Radio Support
- COR polarity jumper, and -6dB/Octave de-emphasis jumper per port
- DTMF valid LED allows visual indication of valid received tone
- Each port has its own DB-9 Connector for radio port connection
- Small board outline, only 4.50" x 7.50" : Low Power, only 25mA Current Draw
- Each Link port can be expandable up to 3 links using the RLC-6 Link Expansion
- Optional 19" Rack Mount Cabinet for mounting the RLC-1, the RLC-6 Boards

All These Features for Only:

The HatCam

Thanks to the latest in miniature video technology, the ability to carry a complete ATV transmitter and camera on top of your hat is now a reality. Imagine an extremely portable ATV system that weighs in at under eight ounces (with a nine-volt battery) and gives you a range of thousands of feet. With the HatCam system, you only need to turn your head to point the camera. This is the perfect setup for special events, hamfests and ATV demos. No cumbersome clutter of cables are needed to hook up this station—just put on your hat and you're ready to transmit.

The HatCam, shown in Photo A, was designed by Jeff Brown N8UEJ and Dave Pelaez AH2AR/8, and first shown at the 1992 Dayton Hamvention. There

are two items that make the HatCam a reality. The four-ounce miniature TV camera from Micro Video Products (the MVP Series V) and the Micro-ATV transmitter described in the July 1991 issue of 73, page 9. The Micro-ATV transmitter is the size of a postage stamp and puts out enough power (80 mW) for a decent range.

The MVP-V Miniature TV Camera

The truly remarkable achievement is the incredibly small B/W TV camera from Micro Video Products [Telephone: (800) 473-0538]. The MVP-V (see Photo B) measures just 1-1/4" square by 2-1/4" long. It fits neatly in the palm of your hand and is the smallest camera I've seen so far. At \$289.95, it's surprisingly affordable for a camera of its size. The MVP-V has a built-in wide angle lens, an automatic electronic iris and an excellent light sensitivity of 2 lux. Its small size and superb performance should make it a popular

Photo B. Close-up view of the Micro Video Products miniature video camera (MVP Series V).

choice for R/C model ATV, Handle-Lookies, as well as a hamshack camera you can mount just about anywhere.

Build Your Own HatCam

Once you've acquired the transmitter and TV camera, all you need is a baseball cap. The MVP-V TV camera should be mounted securely to the bill of the cap with a 3/8" long 1/4-20 bolt. Try to mount the camera near the edge of the bill so that the hat isn't in the field of view. Next, run the video/power cable around the edge of the cap so that you have enough cable to reach the back of the cap.

Mount the ATV transmitter in a small plastic project box (a case from a kid's walkie-talkie was used for the HatCam shown in Photo A). Make sure you have room in the box for one or two 9-volt batteries, the video and antenna connectors, and the power switch. You can use a small 450 MHz rubber duck for the antenna. If you modify the case from a kid's walkie-talkie, you can use the on-board telescoping whip for the ATV antenna. Now just clip your transmitter to the plastic strap on the back of your baseball cap, hook up the cable, and you're ready for some real portable ATV fun!

You can expect about 30 minutes of life if you operate both the camera and the transmitter from one 9-volt battery. Two batteries in parallel should give you upwards of an hour. If you run with the batteries in par-

allel, be sure to wire a 1N4001 blocking diode from the positive terminal of each battery to the common positive supply point. As an alternative, you can power the transmitter and camera from separate batteries.

The Future

Of course you can use the miniature components of the HatCam for your own special applications. You no longer need a 1/4-scale R/C plane to carry a large ATV transmitter and camera. Many of the smaller planes should have enough lift to fly this system. R/C cars and even boats are other likely candidates. How about a Dog-Cam? Now you can see your pet's point of view as it catches a Frisbee!

I imagine that as cameras and transmitters get even smaller, you might even see a practical version of the Dick Tracy video wristwatch in the not-too-distant future.

Photo A. Jeff Brown N8UEJ demonstrates the HatCam. The camera is attached to the bill of the hat and the transmitter clips onto the plastic strap on the back.

Wayne is mad as helland he doesn't want you to take it anymore! Declare War! On Our Lousy Government

Fed up with the mess in Washington?
The mess in your state capital?
Poverty, crime, our failing schools?
Wayne Green has solutions.
Clever solutions.

Wayne Green's unique reasoning is intriguing — even delightful. Whether you are horrified by his proposals or you embrace them, it is impossible to ignore the basic lesson he presents: It is time to bring logic — not emotions — to bear on America's dilemmas. His spin on America in the 90's helps us to understand how simple the seemingly complex issues are. All it takes is looking at them from an entirely new viewpoint.

Now available in one complete volume, *Declare War!* is full of thought provoking ideas and solutions to some of the most difficult problems facing our country today.

Regular price: \$12.95

Special For 73 Readers Only—\$10.00 (plus \$3.50 shipping&handling)

RTTY LOOP

Continued from page 55

don't advise it. It is hard to match the convenience and stability of a commercial rig for these frequencies, and who says you have to buy new? Ask around at a local club, check hamfests, network through friends and local radio stores. If you keep your eyes open, I suspect you will be able to pick up a secondhand, slightly older, 2 meter radio for well within your budget. Who knows, someone reading this might just offer to help.

Getting on Packet

Matthew's second question revolves around packet. He says that, "while perusing the ads in the magazines, I read an article or two about packet radio. I've heard that packets are relayed all across the country. How does this work? I assume I broadcast the message and a local repeater will pass it along. How do I get started in this? It sounds a whole lot cheaper than calling long-distance!"

Well, before we get to the first part of the question, let's deal with the end. Don't forget that no matter what, ham radio is non-commercial communication that cannot be used to replace commercial carriers. So, unless your father is a ham, better stay with the phone company, or at least one of them.

Now, packet communication involves bundling little packets of digital

communications together, each packet of which is addressed to where it should go. You send these packets to either the addressee or another station which can relay it along. That relay station, an automated update of the old message relay system which founded a radio relay league, is a digipeater. Don't confuse this with a conventional VHF repeater. Whereas the repeater merely retransmits the received audio on another frequency, the digipeater regenerates the received data, thus cleaning up the data. More on this in future columns.

Digital communications span the spectrum from old-fashioned radioteletype to the latest computer wizardry, and "RTTY Loop" loops around the same neighborhood. For example, volumes one and two of the PC compatible RTTY programs remain available, as is a collection of PC archiving utilities. Each collection is over a megabyte in size, and will fit on a high density 5" or 3.5" disk, or on a bunch of low capacity ones. To receive your copies, send me sufficient media, a postage-paid return disk mailer, two dollars in US funds per disk, and be sure to tell me which collection you want. Send it all to me at the above address, and I'll turn it around real soon. Don't forget to send me your comments and questions as well; to the address above, or via CompuServe (ppn 75036.2501), Delphi (username MarcWA3AJR), or America Online (screen name MarcWA3AJR).

ANY RIG—ANY ANTENNA AUTOMATICALLY SMARTTUNER™

Let's get frank about HF antennas. Most hams try to put resonant antennas up for every band. For those with the room, great! But for the rest of us, limited to perhaps a single long wire or some other compromise antenna, the SGC SMARTTUNER is the ideal solution. Its onboard computer selects exactly the right inductance and capacitance from more than one half million possible combinations. Then it remembers the setting so your rig will retune in 10 milliseconds. It's waterproof, too, built to exacting standards.

Collecting Surplus Surface Mount Components

This month we'll cover one method to help you stock your junk box with some exotic components. Normally, the removal of the miniature components presents a large problem when undertaken in mass, but I think you will be quite pleasantly surprised to find out how well this method works.

First, a little about the components that can be reclaimed. Surface mount components, being very small, make new construction respectably smaller than conventional circuits.

A quick example is a standard IC. Take any basic device and you will find that it is available not only in the standard 14- or 16-pin plastic package that we are all familiar with, but most come in surface mount packages as well. The main difference is size. The standard 14-pin IC is just over an inch long, with pin-to-pin spacing of 0.1". The surface mount equivalent is less than half the length and about one quarter the height. See Figure 1 for the size comparison.

ICs are not the only components that come in these miniature packages. Resistors, capacitors, inductors, transistors and a lot more are coming packaged this way. In fact, I just found in surplus several mixers for RF that work over their range of 5 MHz to 2000 MHz. A lot of exotic surface mount components are being used in electronic equipment manufacture due to size constraints. This should make more of the older surface mount systems available in the surplus or scrap market for amateur use. Be observant and you might locate a gold mine in surplus components in your local area.

One problem that has hung on with these packages getting smaller and

smaller is repairing or modifying circuits. Most people have difficulty removing a chip capacitor as it is very small and must be desoldered on both ends to remove it from a PC board. Why are surplus surface mount components so attractive when you can't easily unsolder them with a soldering iron? Because you don't use a soldering iron. What you want to do is advance into the 21st century in your soldering techniques. I don't propose that you go out and purchase a \$1,000 soldering station. No, what you want to do is to spend about \$20 and be able to have some of the best methods of soldering (or, in our case, unsoldering) at your fingertips. What device can you purchase for \$20? A heat gun. This device is normally used for removing paint by the blistering method, then the blistered paint is scraped off. In our application you will use this same heat gun for electronic component unsoldering, or shrink tubing applications.

D-text: The heat gun has limitations, but as long as you know that soft plastic IC sockets and similar devices will be affected by the gun's intense heat (melted) it will be no problem. Sockets and such can be removed with care, as can some soft plastic components, but I don't see much advantage to keeping them. I find that I want the ICs and electrolytes as well as the tantalums in preference to plastic mounting hardware. I don't bother with resistors, although they come loose free for the ride. These heat guns are capable of blowing a hot 700 to 800 degree blast of air in a stream quite similar to a hair dryer. This will heat up the solder in about two minutes of air flowing about the solder junctions in the air stream.

Before using a heat gun to strip a PC board of components you can use a soldering iron and an X-Acto™ knife or some other means to gently lift each lead of delicate components. When you start to unsolder a PC

Photo A. Components removed with a heat gun. Note the clean pins, even on a 40-pin socket removed from a 386-25 PC board. The 20-pin chips under the 16 MHz crystal show dirty solder leads. These chips were pulled too soon—not all of the solder was allowed to flow before the chip was pulled.

board, direct the heat gun's nozzle to an area on the backside of a PC board to remove conventional chip components first. In some cases you might just have to tap the board to jostle loose surface mount components, letting them drop to a paper below for collection.

In using a heat gun, apply the exhaust (much like a hair dryer, only much hotter) to the PC board area to be heated and position the gun about half an inch from the surface of the board. Don't get too close as this will only burn the PC board. A half inch to an inch is about right. You will have to do a little experimenting with this technique and I suggest a scrap of PC board to try for a first attempt. I have found that positioning the PC board securely in a bench or drill vice will allow you to work rapidly on it. Position the board vertically for conventional rear-soldered PC boards and horizontally for surface mount boards. This leaves both hands free—one for the heat gun and the other for tapping or gently removing components with an X-Acto knife.

Bring the solder to molten temperature around the components to be removed. It will be very apparent as some of them will squirm about their solder pads. This takes about two minutes for the initial heat application. After that, the nearby components take a much shorter time to detach from the board. Some of the ICs can be removed with forceps by gentle lifting (that is, assuming that the component leads were not bent when they were originally inserted on the PC board).

This process sounds unbelievable but in actual practice it works quite well. Last night I unsoldered a PC board to recover some connectors and ICs from a defective 386-25 MHz computer motherboard. I completed removing all the components from the board in about 10 minutes. The board was empty of all chips that were soldered, leaving just the sockets and a

few of the other components. Bypass capacitors, clock oscillators, 40-pin sockets, etc., were all removed in this operation with the heat gun.

The procedure to use with surface mount components is much the same, but instead of directing the heat to the rear of the board, direct it to the component side where the surface mount part is attached. This works well to remove top-mount components on the PC board. When a heat gun is used components retain their exact form and are not distorted in the removal process. If a conventional soldering iron (pencil type) is used to remove a four-leaded transistor, the leads each have to be heated and lifted with a knife. When this operation is completed, the part is removed but all four leads have been bent or otherwise deformed in the process and sometimes are quite resistant to being removed intact. With the heat gun, the only possible damage that can be subjected to the part is excessive heat. Most devices take the operation with the heat gun well. Just use reason and common sense. In no case should the PC board burn or blister or smoke—if it does you're too close and there's too much heat. Back off and give it a little time. Don't try to rush here.

Don't rush the solder during its heating. The part can be pulled off prematurely, but if you wait a short time it will come off quite clean without effort. For instance, when removing a 14-pin or even a 40-pin chip, heat the board from the solder side for about two minutes to bring the section of board to temperature and watch the solder on the opposite side of the board. It will soon show signs of being molten. Don't pull the IC or socket just yet, even if it seems to come with a little pressure. If you wait another 15 seconds or so it will pull off without pressure and the board will wick off the excess solder from the part, making the pins on the IC clean. You will not have to clean up the part later if you take time in this step.

Figure 1. Standard 14-pin DIP, compared to a surface mount IC. The 14-pin DIP mounts through holes drilled in the PC board. Surface mount means just that—it is soldered on the component side of the PC board (no holes).

I suggest you invest in a similar unit that can be picked up in a well-stocked hardware store. On the West Coast they can be obtained in the "Home Depot" and "Home Club" type home handyman stores. You should not have trouble finding a similar heat gun as this type of store sells just about everything, including the kitchen sink. I checked with Sears and they have two models of heat gun to chose from. The first is a Wagner Model 15115, which heats to 850 degrees, priced at \$24.99. The second is a variable heat control type, also from Wagner, with heat to 1100 degrees, priced at \$29.99.

I have not tried either of these two models from Sears, but they are quite similar to the unit I picked up from a local hardware store. My heat gun is dual-heat, stating low heat of 700 degrees and high heat of about 1500 degrees. It's called a "Super Stripper Mod. 1500" and is made in Taiwan. I don't think the upper temperature is actually reached; I have no way to measure its temperature output. Needless to say, a good AC power connection is required as these heat guns draw quite a few amps to do their job efficiently. Extension cords should not be used as they may limit output. Some more common extension cords are constructed from small diameter conductors and can't support the higher currents needed by the heat gun.

Mailbox Comments

Oscar Franco LU7ATH, from Argentina, recently corresponded with me and is working on setting up some YIG oscillators for the microwave bands below 5 GHz. I sent him a PC board for the 5.6 GHz band to assist his operation. I also sent a few SRA-11 mixers that are good to 2000 MHz RF. I hope these assist him in construction projects in Argentina.

The biggest problem in shipping components to others is the distance and assurance that the components do arrive. Air shipment and insurance can be quite costly. For us here, it's all too easy to hop in the car and go to our local parts supplier. We should all take another look and be quite thankful that we have the opportunity and good fortune to have electronic super-markets, or even a Radio Shack, from which to pick up simple parts. They are so easy that we forget what it's like in other parts of the world.

Another traveler I have communicated with is Thad N2QMG. Thad's current project is a 10 GHz wideband FM transceiver and CW IDer. I have to redesign the PC board for the IDer to make it more compact and use fewer jumpers, but that is just a matter of time on my part. There's always a new PC board to design.

Jean-Yves Trudie VE2BFU is chair of a group of students in Quebec who are quite interested in weather applications of radar. He is looking for any

inexpensive components to help out on projects. He refers to the column on the 10 GHz amplifier in the September 1992 issue of 73. He questions, can it be driven from a low power Gunn oscillator? Well, the answer is yes. I use a simple 10 mW Gunn oscillator and 30 dB attenuation on my work bench to replace all other systems in amplifier testing. When used in conjunction with the variable 30 dB waveguide attenuator, it can be preset to some low level to test other devices. I use it to provide power (RF drive) to test traveling wave amplifiers on 10 GHz.

TWTs require about +1 dBm to drive to full amplification of 10 watts output. The Gunn oscillator works very well in this application. It can be used in conjunction with a solid-state amplifier just as well. However, I must stress the output attenuator as it is a must in all applications. Don't ever overdrive amplifiers as it could result in destruction of your test device, depending on the power level used. See Figure 1, my test 10 GHz Gunn oscillator. The only drawback with a Gunn oscillator is frequency instability, but as a power driving source they work exceedingly well and are inexpensive.

A letter from Hugh Duff VE3OYH requests permission to use the amplifier schematic I published in the September 1989 issue of 73 magazine. It concerned an SSB biasing scheme and power amplifier schemat-

ic for a 6 meter amp I constructed for my IC-551. The design was not special. It used application notes that were available from transistor manufacturing companies at that time. What I did was try the circuit (class C) and modify it to an SSB class of circuit for linear operation—kind of a class A/B type of operation. In class C no DC power is drawn from the device until driven by RF. In class B's and later class A's, some current is drawn without RF drive to set up the stage towards linear operation.

Also, Hugh is looking for some of the FM accessory boards for the IC-551. Any help out there on the PC boards? Contact Hugh Duff VE3OYH, 136 Baronwood Crt., Brampton, Ontario, Canada L6V-3H8.

Steve Carlisle VE7AHL writes that he has obtained some microwave waveguide material for 10 GHz and would be willing to make some available for interested parties. Steve is located in Port Hardy, B.C., Canada, and can be contacted at (604) 949-8588 (after 6 p.m. PST). The material he has includes 12-foot sections of WG-16 (1/2" by 1" o.d.) and a variety of bends and straight sections. Detector mounts and hybrids are also available. Contact Steve for particulars.

Well, that's it for this month. As always, I will be glad to answer questions regarding this and other related subjects. Please send an SASE for prompt reply. 73 Chuck WB6IGP

Notes from FN42

Reward time is here again! What am I talking about? The rewards we receive when we help others become hams. Also rewarding is seeing those we helped become hams last year volunteer to help in this year's classes.

How easy (or hard) is it to host a ham class? I can only speak for myself, but I don't think that it is too hard if one person will provide the coordination and many others get involved and help teach the lessons. What it takes is having the vision to make it happen, letting others know about that vision, and talking it up to those who are active hams.

Luckily, the effort in the Keene, New Hampshire, area really started last year after completing the previous ham class and examinations. All those involved last year said that they wanted to do it again. It was decided to continue to offer the classes once each year. We decided that the classes worked best during the school year, preferably between January and June, so we set a tentative start date in February.

Around December, discussion of the ham classes started to flow on the radio and over coffee. Those of us who helped teach the classes last year asked Doug KD1GJ if he would lead the effort again this year, and he agreed. Off to a good beginning.

January arrives. Meeting time

again, this time to decide when to start the sessions and who was going to teach which modules. Before we decided on a date, Doug announced that a new ham club in the area, the Cheshire County DX Amateur Radio Club, was willing to sponsor the effort. It is certainly nice to have the support of a larger group of hams.

The decision was made to offer the classes one evening a week and to go for 10 weeks, with the test in the 11th week. Each class would last for approximately 2-1/2 hours, with a break, and cover three to four modules. Doug, organized as usual, brought the syllabus from last year, and then it was time to select modules to teach. That really took very little time because just about all the modules (with a few exceptions) would be taught by the person who taught it last year.

We are very lucky that one of the largest employers in Keene, Markem Corporation, is also very appreciative of the hams within its organization and is allowing us to hold the classes in its facilities. Markem is also allowing VE testing at the same location four times each year.

February 15th is just several weeks away as I write this column. Lesson plans are being put together by the instructors and hands-on demonstrations are being developed. The old excitement is coming back and starting to bubble to the surface. If you have never felt that excitement, try it, you'll like it!

Well, I'll let you know in the future how things work out, but I bet they will turn out great.

Lastly, I hope that you enjoy the two QSL cards from Japan. There is something about the artistry and colors from Japan that set their pictures and architecture apart from the rest of the world. I am very lucky that David sent two of his QSL cards because one of them is going to stay here on my wall. Now I just have to find him on the air to really deserve it.

Until next month.
73—Amie, N1BAC

Roundup

Pakistan It is with great happiness that the Larkana Amateur & SW Listeners Club celebrated its 2nd anniversary on 6 Nov. 1992.

We invited many people to celebrate with us, including two

Photo A. A few members of the Larkana Amateur & SW Listeners Club.

Canadian hams, Mr. Rod Black and Mr. Mark Naylor, who are now working in Pakistan with a Christian mission. Mr. Black briefly informed the audience about the fantastic hobby of ham radio and donated some books to our club. After the program was over, 20 interested people filled out the membership forms of the club. We have about 50 books about electronics and amateur radio in our library.

Our radio equipment presently consists of a Drake TRM-34 (100 watts) SSB Marine transceiver that operates on the 2, 4, and 8 MHz bands. Does anyone know if this radio can be converted to the ham bands, or would anyone like to exchange this radio for an SSB QRP transceiver? The radio would have to have the 20 meter band. We also have a vintage Radio Holland Type BC 348JW communication receiver with frequency coverage of 200 kHz to 18 MHz in six bands. We are interested in trading this radio as well for an SSB QRP radio. As you can see, we have no radios to get on the air because of the great expense, so we would definitely appreciate anything that you might have that you could donate to us or trade with us.

Please communicate with us at this address: Arshad H. Quadri (AP2AHQ), Larkana Amateur & SW Listeners Club, No 1989/A 1, Shaikh Street, Karma Bagh Larkana, 77150, (Sindh) Pakistan.

Russia Downloaded from packet, initiated by Sandy Lynch WA6BXH: The following message was recently received here from Andy RW3AH/WL7AP. I think he and Ed NT2X wrote it together; the info may be of interest to others. 73 de Sandy WA6BXH/7J1ABV [WA6BXH @ N0ARY].

Ham Radio in CIS Becoming Expensive There are serious troubles looming on the horizon for the amateurs of the former USSR. Obsessed with "market economy," people in charge of Amateur Radio Service on the government level have imposed (or will impose very soon) substantial fees for the privilege of operating on the air.

The First Class license (equivalent of the US Extra) will cost a ham 120 rubles per annum. To enter any contests, one would fork over 240 rubles per year, in addition to the above. It won't matter if you run 100 watts or 10

Photo B. QSL card of JR6RL.

Photo C. The beautiful QSL card of 7J6CBQ, David Cowhig, Ambassador to Okinawa, Japan.

kW. Special calls call for yet more money. In US currency this doesn't look like much (\$1 = 500 rubles), but it sets a dangerous pattern—pay for what once was free, and expect an increase anytime. The opinions of hams ops were never requested, it seems.

In addition, getting a contest certificate via the bureau would cost five rubles, receiving a single card via the bureau now costs 50 kopecks, sending a single card abroad via the bureau would cost two rubles 15 kopecks. An airmail letter from Russia to anywhere in the world now costs 75 rubles.

Since the prevailing majority of hams can't afford to send airmail letters (the average salary now stands at three to four thousands rubles per month) in quantity, and because the foreign mail isn't getting through to Russia, those U-cards will become very rare indeed very soon. Moscow hams report piles upon piles of incoming QSLs at Box 88 that don't and won't get processed. The bureau is broke and can't pay its employees or its own mailing expenses. Again, hold onto your CIS cards, don't mail them over there until the situation is resolved.

On the related subject: January 1993 was set as a time frame for the changeover of current amateur call-sign allocations to a new system.

Ninety-five percent of all Ukrainian calls will change as well as a substantial amount of Russian calls, if the new system is implemented. Other republics will see a full 100% change of existing calls. As was announced earlier, the new allocations were assigned without any consultations with hams, thus the amateur community of the former USSR republics is in a state of turmoil. Nobody knows what will take place, when and how.

Letters were sent to the ITU, trying to stop the new assignment; government offices responsible for communications were petitioned without any obvious results. There is talk about having hams retain the present call-sign system, while commercial and utility calls would be converted. At this time, it is all pure speculation and no decisions on this explosive topic were rendered. There would be no special calls assigned within the CIS for 1993, I was told, pending the outcome of the above.

As always, we will provide more details as they become available.

73 de Andy RW3AH/WL7AP, 19 Jan. 1993, RW3AH @ RK3KP#MSK. RUS.EU

Switzerland *From the International Telecommunication Union (ITU) Press:* The ITU has issued the first series of telecommunication indicators covering all republics of the former

Soviet Union: Commonwealth of Independent States (CIS), the Baltic States, and the Republic of Georgia.

A joint collaboration of the ITU's Telecommunications Development Bureau and the OECD Centre for Co-Operation with the European Economies in Transition, Telecommunication Indicators of the Former Soviet Union highlights the current state of telecommunications in the region. It has over 30 tables and charts and includes regional totals and averages.

An analysis of the data shows that the telecommunication sector has been characterized by under-investment over a long period, resulting in an urgent need for network modernization to meet the requirements of the population and the emerging market economies.

The supply of telecommunication services also varies greatly from one republic to another, with an average of main telephone lines per 100 inhabitants for the former Soviet Union of 14 (Baltic states average over 20, the Central Asian republics less than 10, and Belarus, Ukraine, and the Russian Federation close to the average).

Highlights of the statistical compilations include: an official waiting list of over 18 million lines (about half the number of existing subscribers, which probably underestimates the total demand); automatic local networks but

with low levels of digitization and old exchanges; an estimated investment of US\$90 billion to attain a telephone density of 30 main lines per 100 inhabitants by the year 2005, requiring the installation of 60 million main lines; an average level of telecommunications development about the same as Central and Eastern Europe and similar to the situation in Western Europe in the 1970s.

The data is available both in hard copy and diskette formats with STARS (Socioeconomic Time Series Access and Retrieval System)—a user-friendly retrieval software for use with microcomputers. For more information and permission to reproduce any part of the publication, please contact: Mr. Michael Mingos, Information Services/Telecommunications Development Bureau, International Telecommunication Union, Place des Nations, CH-1211 Geneva 20, Switzerland. Telephone: +41 22 730 5519; FAX: +41 22 730 5484.

CIRCLE 131 ON READER SERVICE CARD

sador Armin Meyer W3ACE, who served as US Ambassador to Japan 1970-1973. Ambassador Meyer told me once that his security guards were very alarmed one day in the early '70s in Tokyo when his car was rushed by a group of Japanese men. When they got close to the car the men began waving their QSL cards at Ambassador Meyer! Perhaps it was Ambassador Meyer's high-level ham enthusiasm that inspired the Japan-US reciprocal licensing agreement which came a few years later.

December in Okinawa, as in the rest of Japan, brings forget-the-old-year parties (bonenkai) for office workers and hams alike. During December I went to bonenkais of the southern Okinawa 145.19 MHz foxhunting group and of the central Okinawa 2 meter FM group. A week later Yamamoto-san JS6HGV of the foxhunting group took me on a two-hour foxhunt all over Urasoe City, ending with an impromptu meeting over coffee and cakes under the stars. Lots of fun even though Yamamoto-san and I were the last ones to find the fox!

Okinawa blended the cultures of south Asia, China and Japan to create its own unique culture. Awamori, a powerful Okinawan drink made famous by the Japanese actor Marlon Brando in "Teahouse of the August Moon," was brought back to Okinawa

500 years ago from Thailand by Ryukyu Kingdom sailors. Okinawan music and dance, which are quite distinct in beat and style from that of the rest of Japan, owes much to the instruments and music of Indonesia and India. After World War II the United States had some influence on Okinawa, introducing universal education, the first university (Ryukyu University) and root beer. Their very cosmopolitan history has made the Okinawans the friendliest and most internationally minded of all the Japanese. The Okinawans sum up their attitude in the Okinawan dialect phrase "ichariba chode," which can be translated as "aloha" or as "to be brothers from the first meeting."

A new historical novel about the 17th century Ryukyu Kingdom, *The Winds of the Ryukyus*, by Chin Shunshin, now an NHK TV series, has stimulated a tremendous revival of interest in Okinawan history and culture. Chinese goods acquired in exchanges with Ming China through the Ryukyu Kingdom tribute missions and Chinese embassies to the Ryukyu Kingdom capital at Shuri were used to trade throughout South Asia and Japan. Okinawans had a practical monopoly on the China trade since Ming China traded directly only with its loyal tributary state in Okinawa and Chinese merchants were forbidden to travel abroad. My QSL card, which I

am able to use thanks to the kind permission of the Urasoe City Museum of Art, shows tribute ships which carried Okinawan presents to the Ming Emperor.

On April 1, 1993, a new Japanese law charges user fees to all users of the radio spectrum. This is on top of the current fees which radio stations pay today. For example, my 50-watt fixed/mobile ham license costs about \$30 per year to renew. Even my 50 watts is high—most Japanese hams have third- or fourth-class licenses and run 10-25 watts. The initial license fee and renewal fee is on a sliding scale which increases with transmitter power output. Japanese hams will pay 500 yen (US \$4), while radio broadcasters will pay 29,700 yen (\$300) annually. This new Japanese law is intended to raise money to regulate licensed stations and to detect and close down unlawful radio stations. In 1990 there were an estimated seven million lawful radio stations and 1.2 million illegal radio stations operating in Japan. Another goal is to boost radio spectrum use efficiency.

Similar efforts to boost spectrum efficiency by user fees and other methods are also being considered by the US National Telecommunications and Information Administration (NTIA) and the US Congress. NTIA administrator Janice Obuchowski has com-

pared the sale of radio spectrum in order to improve spectrum utilization efficiency to the transfer of public grazing lands to private ownership in 17th and 18th century England, which economists credit with greatly boosting agricultural productivity. Today (January 3) Song BY5HZ, in Hangzhou, China, told me that the Chinese government has decided to allow Chinese hams to set up ham stations in their own homes. Song, a junior high school teacher, has held his own personal call sign BG5FA for about a year but beginning February 20, 1993, he will be allowed to operate a home station. Song told me that some of the first Chinese hams, such as BA1CY in Beijing, have been allowed to operate from a private home for about a year. Now this privilege is being extended to more recent licensees, such as Song. This is wonderful news for Chinese ham radio operators and for hams around the world. Perhaps many of the Chinese hams who couldn't get on the air after graduating from school will return to the air.

A reminder to all who wish to get a license when coming to Japan: The best way to get information is to write to the JARL International Section, 14-2 Sugamo 1-Chrome Toshima-Ku, Tokyo 170 Japan.

(David's contribution will be continued next month.—Arnie)

Continued from page 66

My *Frontiers* publication was mainly

I was having so much fun that I stayed on as editor a couple years longer than I should have. But I've

I read a lot of magazines, so I have to be able to interpret computerese, legalese, governmentese, medicalese, hamese, hi-fi-ese, and educationese. It's a challenge to try and figure out what some professor is trying to say.

For my part, when I'm on the air I avoid jargon and stick to plain English. I have problems with interference, not QRM. I go to bed instead of modulating the mattress. I answer the phone instead of the landline. But then I am very resistant to talking about my transceiver and antenna, much preferring to talk about what the other chap does, what else he's interested in, what he likes about where he lives and so on. You probably wouldn't like it at all.

CIRCLE 54 ON READER SERVICE CARD

NEW PRODUCTS

Compiled by Hope Currier

C O M E T
Antenna has introduced the newest addition to their extensive line of multiband antennas, the CH-32 "Miracle Baby" Mini HT Antenna for 2m/70 cm. The CH-32 has surprising performance, is only 1.75 inches tall, and has a black matte

NCG/COMET

finish and a BNC connector. It is designed with a pivoting head, absorbing shock and protecting the radio's connector from damage. The CH-32 meets the modern operator's need for a small, compact antenna that easily works the nearby repeater systems and is useful for communicating at hamfests, on Field Day, while doing tower work, etc. Its small size makes it inconspicuous and proportionate in size to the newest HT transceivers.

For the price and more information, contact NCG, 1275 North Grove St., Anaheim CA 92806; (714) 630-4541, (800) 962-2611, Fax: (714) 630-7024. Or circle Reader Service No. 201.

ELECTRON PROCESSING

Electron Processing has announced a device to greatly improve scanner and shortwave reception. The AFBOX-1 allows you to connect your receiver to an existing hi-fi stereo system to extract the best fidelity and clearest sound obtainable from your scanner or shortwave receiver. By connecting to a stereo system scanner,

listeners can often understand previously unintelligible background conversations. Shortwave listeners can finally enjoy the full fidelity with which the broadcasts were meant to be heard. Connection to the external speaker jack of the receiver and the hi-fi auxiliary input jacks is easy with the supplied connectors. An isolation transformer and passive attenuator

assure clean, noise- and hum-free sound on both right and left channels. The AFBOX-1 can be connected to a VCR for up to six hours of quality recording.

The AFBOX-1 is \$30 plus \$5 S & H. For more information, contact Electron Processing, Inc., P.O. Box 68, Cedar MI 49621; (616) 228-7020. Or circle Reader Service No. 205.

G & P ENGINEERING

G & P Engineering has announced a new style of antenna mounting system called the "N-PAM" unit. The N-PAM unit will mount on the roof without drilling holes into the roof. It will mount on any roof at any pitch from flat to a

12/12 pitch, and will allow use on roofs with 16" o.c., 24" o.c., stick-built or truss systems. Basic systems include single or dual tray units with a 2" mast 3' high—ideal for a tribander/VHF-UHF system. Options include a 5' or 7' mast. The 7' mast can be used with the largest OSCAR antenna system or stacked yagis.

All mounts are made of steel and are primed and painted with a durable and hard epoxy paint, black, to blend with most roof shingle colors. For prices and more information, contact G & P Engineering, 4943 Finch Court, Stephens City VA 22655; (703) 869-4530, Fax: (703) 869-5116. Or circle Reader Service No. 204.

BackPack Solar?

10 watt DesertStorm panel is size of open 73 magazine, weighs 1lb, and delivers 600mA for 12v charging or direct operation. Tough. Solid, with no glass to break. So rugged Uncle Sam used this for spotter communications and portable repeaters in Desert Storm. Ready to use. \$169. Add \$5 S&H. Info \$1.

The Best Scanner Use Antenna! The FLYTECRAFT™ Model CFN 16 Element Wideband VHF/UHF Antenna

Designed by
Emmy-Winning
Network TV Engineer
Steve Flyte,
K7SF

- The Model CFN is the ultimate compact, rugged antenna for 50 to 1.3 GHz use. (Transmit from 144 to 1.3 GHz)
- Average SWR - 1.5 across transmit range.
- Amateur radio licensees operate all bands - 2M, 220, 450, 900, and 1.2 GHz
- Novices! Ideal for operation in 220 or 1.2 GHz band for which you have privileges.
- Low vertical angle radiation
- Large capture area
- Unity gain
- Use indoors or out - CFN is lightweight, but tough - withstands hurricane-force winds.
- Instant assembly - ideal for permanent, portable, or Field Day!
- Attractive, strong design. Unique, futuristic appearance.

Built with pride & sold worldwide - FLYTECRAFT™ USA

CAL-AV LABS

CAL-AV Labs, Inc. has introduced the Spirit™ series of dual-paddle Morse keys, which incorporate advanced design and a new technology to eliminate contacts and all other moving parts. Designed for optimum performance in a traditional operating environment, the Spirit provides familiar functionality very similar to a mechanical key. Its solid-state-force sensors activate when a given, preset force is exceeded. Independent left and right adjustments have infinite resolution, and will accommodate operators with a light or heavy touch. The unit weighs five pounds and will not move

from its desired desktop location.

The Spirit is currently available as a limited-production edition for the discerning enthusiast. Its uncompromising quality is evident in its polished, solid brass construction. Each key is individually serialized and can be further customized to a user's preferences: engraving of an individual's name or call letters is available; chrome or gold plating are optional. Detachable cabling accommodates a wide variety of keyers. Prices start at \$380. For more information, contact CAL-AV Labs, Inc., 515-B Westchester Drive, Campbell CA 95008; (408) 369-1000. Or circle Reader Service No. 203.

LARSEN ANTENNAS

Larsen Electronics' new KG 1290 is the first on-glass antenna for amateur application on the 1290 MHz band. Engineered for ham use in North America and Japan, the unit covers the bandwidth from 1235 to 1432 MHz with a VSWR reading below 1.5 to 1. Using a collinear design featuring a 1/2 wave over 1/4 wave, the antenna produces 3 dBd gain. Exceptional performance stems from the patented Kulglass design that places the radiating antenna circuitry in the outside coupler (not inside the vehicle) to maximize efficiency. Model KG 1290 also features a Kulrod copper-plated whip which lets transmit power become signal, not heat resistance.

The suggested retail price is \$59.95. For more information, contact Larsen Antennas, Larsen Electronics, Inc., 3611 N.E. 112th Avenue, P.O. Box 1799, Vancouver WA 98668; (206) 944-7551, Fax: (206) 944-7556. Or circle Reader Service No. 202.

OAK HILLS RESEARCH

The QRP Spirit Transceiver from Oak Hills Research is a single-band kit offered for 80, 40, 30, 20 or 15 meters. It includes an iambic keyer using the latest Curtis Keyer Chip 8044ABM, a Superhet receiver design with a diode ring mixer and an RF preamp, a 4-pole crystal ladder filter followed by an on-board audio filter,

and a switchable HP AGC circuit with manual RF gain control. It also offers 2 watts of audio output with an external speaker jack, VFO tuning with an 8:1 vernier dial covering 100 kHz and RIT, and a sine wave oscillator with frequency and level controls. The kit measures 4" x 6-1/4" x 6-7/8" and weighs 47 oz.

This kit comes complete including the cabinet, all components and instructions. All coils are pre-wound. The price is \$198.95. For more information, contact Oak Hills Research, 20879 Madison St., Big Rapids MI 49307; (616) 796-0920, (800) 842-3748, Fax: (616) 796-6633. Or circle Reader Service No. 206.

Measure Up With Coaxial Dynamics Model 83000A RF Peak Reading Wattmeter

Take a PEAK with Coaxial Dynamics "NEW" Model 83000A, designed to measure both FWD/RFL power in CW and FM systems simply and quickly. Then with a "FLIP" of a switch, measure "PEAK POWER" in most AM, SSB or pulse systems. Our Model 83000A features a complete selection of plug-in-elements plus a 2 year warranty. This makes the Model 83000A an investment worth looking at. So go ahead, take a "PEAK", you'll like "WATT" you see!

SCARED OF THE CODE?

IT'S A SNAP WITH THE ELEGANTLY SIMPLE MORSE TUTOR ADVANCED EDITION FOR BEGINNERS TO EXPERTS—AND BEYOND

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops). Available at dealers, thru QST or 73 or send \$29.95 + \$3 S&H (CA residents add 7.75% tax) to:
GGTE, P.O. Box 3405, Dept. MS,

Is This Frequency In Use?

Is it me, or are people getting stupid? Allow me to relate to you what I experienced last weekend. The names and callsigns have been changed to protect the moronic.

I had been involved in a net on 7.283 MHz for close to an hour. It was a cold, gray Saturday morning, and I was enjoying the net and a second cup of coffee. We had check-ins from locations as far apart as Colorado, Georgia and Nova Scotia. Net control was located in Milwaukee, and he was running slightly more than 900 watts. Conditions on 40 meters were excellent and the band was packed.

A W1 station came on our exact frequency, and without a word of warning started calling a W2 station. His signal was S-9 +20 and just about wiped out the entire Northeast part of the country. I informed him that the frequency was in use, and asked him kindly to move. He never acknowledged that he heard me (knowing his location and my antenna's performance, I am 100% certain that he did).

After a minute or two, he made the same call, and I again asked him to move. Again, no reply. Two or three minutes later, the same scenario. By this time, stations in New York and Nova Scotia had also asked the W1 to move. They were met with the same results I had achieved—silence.

Another five minutes passed without a call. Right at the top of the hour, the W1 came on and started informally calling a net ("Anybody from the XYZ net on frequency?"). The W2 station he had originally called came back to him and they started an informal chat. At the first available break in their seemingly endless discussion about their signal strengths, I keyed up and again informed them that the frequency was in use by another net, and would they please move off frequency.

Now, here comes the really incredible part.

W1: Did you hear that?

W2: Yup, I heard something. I think he said there was another net on this frequency.

W1: Yeah, that's what I heard.

W2: If we move frequencies, the net will never find us. This is our frequency. We've been here for years. They must be a new net (the net I was checked into has been operating for many years at the same time and frequency, though I can't fathom what that has to do with anything).

W1: So, how's my signal now? I just changed over to the other antenna.

The two stations, after acknowledging that they had heard me and that they were aware that another QSO was in progress on the frequency, continued their conversation as if nothing had happened. I couldn't believe it! I again asked them to move, and again they acknowledged that they heard me—with the same results. I heard net control call me for my next transmission, but was wiped off of the net by these two lads. They finally said, "let's move up 500 hertz, to give them a little room." Can you believe it? These weren't a couple of newcomers. Judging from their callsigns, these two lads had each been hams for over 25 years, and yet they thought that moving 500 hertz would do anything? Did these guys know the first thing about radio?

Every area of human endeavor has a set of fundamental rules, guidelines or mutual agreements. All participants in the activity have agreed to abide by these rules. When you drive an automobile, you agree to be sober and to obey certain traffic signals. In this country, you agree to drive on the right side of the road. One of the fundamental agreements that we amateurs make with each other is that we will ask if a frequency is in use before transmitting. We have also agreed that no station or group of stations can lay claim to a particular frequency. This means that there will often be conflicts. When propagation on a particular band shifts, two QSOs could end up on the same frequency. Mature adults should be able to quickly comprehend what is happening, and resolve the dilemma by one of the parties offering to find another frequency (it's amazing how often I've heard 30-minute name-calling sessions as a result of shifting band conditions). When it's time for your net to start, and the frequency you've met on for 20 years is occupied, you should either move, ask the occupants of the frequency to move, or maybe even ask the occupants for a few seconds to inform your net members to stand by and wait.

There are numerous ways to accomplish this basic agreement among all radio amateurs, but we must start from a position of mutual respect and common courtesy. We are not dealing with brain surgery here. Nobody dies if you don't get to hold your net or scheduled contact on a particular frequency at a particular time. Yet, I've often heard suggestions of physically impossible acts and threats of physical violence exchanged between two adults, simply because 10 meters shifted and they found themselves on the same frequency. What is the matter with us?

April's conditions for the upper HF bands appears somewhat "iffy" with many Poor (P) and Fair (F) days in the forecast. It appears that the poorest conditions will be during the first and last days of the month, while the in-between days will range from Fair (F) to Good (G). The best days are likely to center around the 12th and the 22nd, and several days on either side of these dates. The full moon occurs on April 6th.

Use the daily chart to find the best days for your efforts and choose the Band-Time-Country chart to discover when and where to operate. Trends are indicated by hyphenated letters such as F-G meaning Fair-to-Good conditions expected, or P-VP meaning Poor-to-Very-Poor conditions are expected. Remember, however, that these forecasts are not cast in concrete, and that unexpected bonus days or terrible days may occur at almost any time. We're trying to "play percentages" here, so be on the lookout for sudden opportunities. Your best source for trends is WWW at 18 minutes after each hour (I use the 10 MHz signal as the most reliable copy from Arizona). They will tell you the status of the earth's magnetic field and the energy output of the sun during a 24-hour period. The sun's radio energy is measured at a wavelength of 10 cm, which seems to have a good correlation with actual propagation conditions on the HF bands.

April is historically a good month for communication and you can expect DX to the east in early morning hours, short skip during the day, and DX to the west in afternoon hours. The higher the band, the sooner it closes toward evening hours. 20 meters should stay open on Fair or Good days until after dark, while the 10, 12, 15 and 17 meter bands will close around sunset. You may try some DX on 30 meters in the mid-to-late afternoon, lasting until well after dark, although as I write this column, the 30 meter band seems to close soon after dark. 40, 80, and 160 meters are usually quite active into the "wee" hours of the morning, so if you are a "night owl" enjoy the opportunities that abound around 1-5 a.m. local time. During the active spring storm season there will be heavy QRN on many days... but these storms usually

subside after 10 p.m. local time as the solar energy that feeds the storms abates. Solar activity (flux) is dropping to the 100 level as I write, which means that ionization is not as great and does not last as long as a few months ago. Inasmuch as solar flux correlates with DX "conditions" and with the sunspot numbers, it is apparent that we are well on our way to the bottom of Cycle 22. During the DX heyday a few years ago, solar flux values of 200-300 were common.

Choose your days carefully from the chart, and correlate "conditions" with the Time-Band-Country/Area chart for the most likely success. As "conditions" deteriorate, you will need more power than usual to "get through," as well as better antennas.

Microfilm Edition—University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to 73 Amateur Radio Today, P.O. Box 7693, Riverton NJ 08077-7693.

Contract: When's the last time you built something? The act of reading this question has just legally bound you to an agreement with Uncle Wayne whereby you promise to build at least one project within the next 30 days. In fact, why don't you get together with a few of your buddies and all build the same circuit or antenna? If you build from a kit, go ahead and write a review and send it in. OK... What are you waiting for?... Get to work!

NEVER SAY DIE

Wayne Green W2NSD/1

Do You Suppose? Maybe? Now, It's Impossible No Use Even Trying

There's something that's been puzzling me for ages. Actually, now that I come to think of it, there've been several things that have been puzzling me, and which now make sense. Like how come no one has written any really creative classical music in the last 50 to 60 years? Like how come so many readers tell me they don't always agree with my editorials? Like why we Americans put up with the crooks we've been sending to Washington; our crummy post office; our dreadful schools . . . the most expensive and worst in the industrial world . . . and so on.

I've seen the same pattern in amateur radio, with an infinite tolerance for League mendacity, and of course there's this whole CW nonsense.

Yes, I admit I'm probably part of the problem in that I tend to be much too cautious about speaking my mind. Allen Turoff, the chap who invented the game of Boggle and an old car rally buddy of mine, used to call me Wishy-Washy Wayne because I was so hesitant about expressing my opinions . . . and so insecure in them, once they were tried out of me.

Suddenly several things which have been puzzling me fit together and made sense when I read a book by John Gatto. He's the New York State Teacher of the Year you've probably seen on TV, and his book, *Dumbing Us Down — The Hidden Curriculum of Compulsory Schooling*, is a corker. For the few of you who have survived our school system and actually read, I'll make copies available through Uncle Wayne's Bookshelf.

I semi-survived our public school system, but it so numbed me that it wasn't until I went through a new kind of psychotherapy when I was 28 that I was able to actually start thinking. That's when I started reading and building my library. I referred to this therapy when I described how the mind works in my October 1992 editorial. I'll eventually explain how almost anyone can help others to start thinking and stop just reacting.

John Gatto's book is the most devastating indictment of public education I've seen yet. Oh, we've known for

over 10 years that we have one of the worst educational systems in the industrial world . . . which makes up for its terrible results by being one of the most expensive. But what we haven't considered, and what even John Gatto hasn't suggested, is that the end result of this lousy system has been a throttling of creativity and genius, a generally negative approach to new ideas, and a fear of opposing the system.

If you stop and think about it, not only haven't we seen any really outstanding composers in the last 60 years or so, we've also seen a drop in creativity in art, literature, poetry and so on. We've seen a deterioration of the whole country. Now I think I know what's gone wrong.

When I read a book I keep a Highlighter at hand. Well, my Gatto book is an epic in yellow swatches. Unfortunately, since you are a product of our educational system, the chances are that you find books boring, and besides, you know that there's nothing you can do to change things, so why bother. Even so I'm going to make this book available to the few of you who have escaped being totally destroyed by the system and who still have some shreds of interest in understanding what's happened to all of us. It's available from Uncle Wayne's Bookshelf. Once you read it you will want to get copies for what few friends you have who are functionally literate.

What Our Children Are Actually Being Taught

John points out that he teaches seven basic concepts. He teaches confusion by dealing with subjects out of context and not relating them. Curriculums have no coherence.

He teaches class position . . . to envy and fear better classes and have contempt for lower classes and groups. He understands that truth and schoolteaching are incompatible, as Socrates pointed out thousands of years ago.

He teaches indifference . . . that no job is worth finishing, and this is driven home by bells, which stop everything in midstream. Nothing is worth finishing, so why care?

He teaches emotional dependency. Rights do not exist inside a school . . . not even free speech . . . unless the

teacher says they do . . . not even to go to the toilet.

He teaches intellectual dependency. Successful students do the thinking he assigns them, with little resistance and a show of enthusiasm. Curiosity causes trouble, so conformity is rewarded. Wait to be told what to do.

He teaches provisional self-esteem. The lesson of report cards, tests and grades is that children should not trust themselves or their parents, but should rely on the evaluation of certified officials.

He teaches that one can't hide. In school there are no private places. Children must be closely watched if you want to keep them under tight control.

He says, "It is the great triumph of compulsory government monopoly mass-schooling that among even the best of my fellow teachers, and among even the best of my students' parents, only a small number can imagine a different way to do things . . . the truth is that reading, writing, and arithmetic only take about one hundred hours to transmit as long as the audience is eager and willing to learn."

Now is it entirely a coincidence that artistic creativity dwindled as public education took hold? It was started in the mid-1800s by a group of socialists, but didn't take over completely until around 1880, when the militia finally forced parents at gunpoint to send their children to public schools. The system grew in administrative bureaucracy and control through the 1920s.

Gatto says, "When children are given whole lives instead of age-graded ones in cellblocks, they learn to read, write and do arithmetic with ease." He points out, "Out of the 168 hours in each week my children sleep 56. That leaves 112 hours a week out of which to fashion a self. Children watch 55 hours of television a week. That leaves them 57 hours a week in which to grow up. They attend school 30 hours a week, use about eight hours getting ready for it and traveling to and from school, and spend an average of seven hours a week in homework, a total of 45 hours. During that time they are under constant surveillance. That leaves them 12 hours a week out of which to create a unique consciousness. If we allot three hours a week to

evening meals we arrive at a net amount of private time for each child of nine hours per week."

Gatto suggests that this develops dependent personalities and that this has a lot to do with the things that are killing us, such as narcotics, brainless competition, recreational sex, violence, gambling, alcohol, and the accumulation of things as a philosophy. This is what this brand of schooling must inevitably produce.

The results he sees are children who are indifferent to the adult world, who have almost no curiosity, who have a poor sense of the future, who have no sense of the past, are cruel to each other, are uneasy with intimacy and candor, who are materialistic, and who are dependent, passive, and timid when faced with new challenges. Is it any wonder that he says we don't need more schooling, we need less? He believes that education should make you a unique individual, not a conformist.

When I see teenagers with the knees out of their jeans I know I'm looking at conformity-driven kids who have been so brainwashed they're unable to think for themselves. When I get letters from readers who tell me they don't always agree with what I write I know I'm dealing with someone who has never learned to think. No, I don't mean everyone has to agree with everything I write. If that's your reaction, it proves you don't get it . . . and may never "get it." When someone disagrees with me I expect the honesty of them telling me what they don't agree with and what information they have to substantiate their opinion.

It is rare that I meet survivors of our school system who think positively. The normal reaction to ideas is to come up with reasons why they won't work. These are usually emotion-driven, not logic- or thought-driven.

I have to admit to being frustrated by the infinite capacity of the American people to accept the screwing the government is giving them. They may grouse a bit, but are terrified if there's a suggestion that they might be quoted. They are annoyed at the massively crooked Congress they've elected, yet they just re-elected 93% of the incumbents. They watch the exposés of graft on TV with passive frustration. They are annoyed by the \$500 billion savings and loan fraud, which Congress abetted, the billions stolen from one government agency after another, the billions wasted by the military, the lousy performance of the post office, our schools, our health care system, and our inability to deal with welfare, crime, drugs, and so on. But do anything about it? No way!

In amateur radio we have the mindless support of CW. You're just lucky that I am so circumspect about what I think and don't come right out with my opinion. Yes, I know all the rationalizations for CW. I've been hamming for over 50 years, so you have no news for me. Yes, I know CW is lun, I never said it wasn't. And yes, I know you feel

LETTERS

Number 2 on your Feedback card

From the Hamshack

Dan Sealy AA7OA, Astoria OR
Wayne, I have been reading your editorials and responses to our letters for some time, and now I think it's time to respond.

I usually agree with you on most issues. I would, however, like to give you my two cents worth.

First, I don't agree with your constant lambasting of the ARRL. Almost every 73 issue has something bad to say about that organization. Most QST's don't even mention 73. Now, I don't for a moment believe that the ARRL is fairly and equally representing the interests of amateur radio, nor do I blindly agree with much of their policy. I do think that theirs is a case of absolute power corrupted absolutely. I am a member of the ARRL not because I swallow everything the organization says and does without question, but because I at least want to have a vote in how the organization evolves. My vote may count very little in the ARRL scheme of things, but at least I have the right to complain.

For example, you frequently write of the failure of the "incentive licensing" program. I don't think that it has failed at all. I don't think that it is as much of a success as the ARRL would like everyone to believe, but the system does work. I have been a ham for just under two years. When I started, I earned my Technician with HF license. As my involvement with amateur radio grew, I came to realize that the real ticket to amateur radio was access to the HF bands (at least for now). The incentive to upgrade was real and compelling.

I have no problem with a class system for the licenses. If someone wants to be able to use a particular frequency, then work a little and get the appropriate license. It isn't that hard. You have said in many editorials that there is a great big world out there just waiting for some entrepreneur to come along and reap the harvest. I don't think that you meant that one doesn't need to work to achieve those rewards. The world today includes too many who believe that the world owes them a living, and that it isn't necessary to work for what you want.

You constantly write about the elimination of CW in favor of the modern digital modes. Why? What is wrong with CW? If it serves no other purpose than a "rite-of-passage," so be it. There isn't anything wrong with that. Almost everything we do has some form of the rite-of-passage: work, school, sports and others. Few people start out in the job market as supervisors or managers. We work for it. The old-timers usually watch the new kids do the dirty "grunt" work. We work hard to graduate from school.

Along the way we might learn old, outdated material that serves no immediate purpose. The new player on the football team usually warms the bench for the more experienced players.

I have come to appreciate CW as another mode, but I don't think it is the "end-all," "be-all" of amateur radio. Sure, it's old, but so are Model T's and antique airplanes, and I know several who would pay dearly for both. It isn't fast, but it is reliable. You don't need a \$500-to-\$5,000 computer, TNC, and radio to make it work. You can get on the air for very, very little money, and communicate all over the world.

Finally, your statement in the February issue that amateur radio "is a government sponsored entertainment medium" is probably true, but the part about our frequencies being worth "tens of billions of dollars" is false. Sure, some of our frequencies (mainly above 6 meters) are valuable to commercial interests but, with the exception of shortwave broadcast stations, no other commercial interest would put up with the uncertainties of propagation, fading, solar flares, and other conditions which make HF only fairly reliable. Besides, as you stated, the advent of cellular telephones has made our frequencies even less valuable to commercial interests as a communication medium.

By the way, 73 is the only amateur radio magazine I subscribe to, other than receiving QST as part of my "membership."

Dan, your memory is in trouble. There's little connection between the 1964 Incentive Licensing debacle, when the ARRL destroyed the entire American amateur radio manufacturing industry, and the current licensing system. Your memory is also in trouble on CW, which I've never proposed eliminating. I've always been a champion of using CW for fun. You sure have a way of thinking in terms of straw men and then demolishing them. I never suggested our HF frequencies are worth billions. Millions, yes. It's our completely unused microwave allocations that are priceless, as I've emphasized many times ... Wayne

David J. DiCenso WB1CDG I have been reading your magazine for years (since about 1978). I have been pleased at the consistency of the magazine and the enthusiasm about the hobby that is evident in the pages of 73.

The most useful and exciting column that you have offered is Mike Bryce's "QRP" column. That column is the first one that I turn to when I pick

up your magazine. Thanks to Mike Bryce's column, I have dusted off my soldering iron and have become an active builder again. His column's schematics and information are always useful and very helpful. Often when I discard old issues of 73, I make it a point to save the "QRP" column.

Randall M. VanVoorhis KD4DWF, Killeen TX Several months ago you printed a letter of mine mentioning a questionable hard-core push for interesting newcomers in the hobby. The letter got many responses, from "Why did you go and give our club a bad rep?" to "Pretty good," and "Not bad."

Since then I have joined the Air Force and moved from Memphis to Killeen, Texas (aka Ft. Hood Army Installation). Upon my arrival in Killeen I turned on my radio and put out a call and was immediately greeted by Frank N2HNU. After speaking for a while, we exchanged 73s and QRT'd. Later that evening, having received a Poor Man's Packet modem from a friend back in Memphis, I tried to get on the air. Because I had no prior packet experience I gave Frank a quick call to ask some questions. After he spent almost an hour trying to help me over the phone, he gave me the number of the local packet guru. Both calls were toll calls.

We finally got my station up and running. After several packet contacts I ended up on voice with three "local" hams. We chatted and I got to know about them and the area and they got to know a bit about me. These contacts resulted in my getting to know some of the locals, becoming familiar with the different repeaters, and receiving an invitation to join the Temple ARC.

This is another fine example of the hospitality that makes me like to associate with hams. I still have only my No-Code Tech license. I guess I'll get your 20+ wpm tape and upgrade. It's not that far to Extra.

I am a big W2NSD fan and support you 100%. I make a point of mentioning 73 every time I contact one of your advertisers and for your new advertisers, I usually circle their Reader Service number and, of course, in any further contacts 73 is mentioned.

Your point about the audit is a very valid one and I hope the advertisers do take note of your outcome and request an audit of the other publications they may advertise in.

Being in a big state like Texas and close to several "major" cities, I was wondering if you have any plans to attend a hamfest so that I can meet you face to face and shake your hand for all of the excellent work you are doing, not only in ham radio but also in the circus ring called politics.

Randall, I hope your last letter got those cretins to stop and think about their antisocial behavior. We don't need hams like that.

Texas? I don't remember anyone asking me to come down for a ham-

fest recently. Oh, I don't blame 'em. ... I'm probably pretty dull these days, more interested in talking about getting our country fixed than in amateur radio minutia ... even though a big part of my proposals entail generating a million or two new young hams ... Wayne

Chet Smith WB2LUQ, Verona NY 13478 I want to state that I, for one, think the space utilized in 73 for your editorials is put to good use. I've gotten many a good laugh out of some of the responses to your observations. There are, naturally, some of your views that I disagree with. For instance, the idea that everyone who is anyone should have more than adequate supplies of cash to pursue any and all aspects of amateur radio. Also, your less than enthusiastic view on the issue of AM operation. Actually, I see these two points as somewhat related. When I started out, I was still in high school and cash supplies were limited, to say the least. So I went ahead and got my Novice license, and got on the air with a used rig that did have facilities for AM operation. So, not surprisingly, when I upgraded some months later I was able to, and did, get on AM. There were some local guys here who were on so we did make a go of it. No, I'm not on at present, but I do have an old Heath Apache/Mohawk combination that I fully plan to get on with good audio, as far as I can tell. And most AM stays on or near certain agreed frequencies, much like RTTY ops and other alternate mode operators. I simply think that not everybody necessarily has a couple of thousand dollars floating around to use in pursuit of their hobby. I certainly wasn't in that category when I started out, and I'm sure I wasn't the only one.

There's a lot of truth in what you've mentioned from time to time about operating from the other end, getting on from other countries. I came back from over four years in the Marshalls a few months ago, so I have been experienced in that regard. There are all kinds of different clubs on the Island, but KX6BU (Kwajalein Amateur Radio Club, now V7BAX) is the oldest established club there, and had its origins soon after WWII ended.

Over the years I've had some interesting experiences operating at some other club stations' facilities. When I was in the Navy (from 1981 to 1987) I was fortunate to be able to operate from K9NBH, and later from WA4ECY. The club at K9NBH was pretty much defunct, but ECY was a pretty active group. To get back to one of your points, though, I am sure that reviving club stations at high schools and colleges would help immensely, not only in getting more hams, but also in helping us with our sad deficiency in American engineers and techs. I know that I'm not alone in saying that I would have enjoyed school a whole lot more if we could have had some sort of facility at the school.

Unlicensed Ham Operator Heading Back to Prison

The only amateur radio operator ever to be imprisoned for illegally transmitting on ham radio is headed back to the pokey. Richard A. Burton, 48, of Harbor City, California, was sentenced to prison on Monday, February 22, for talking on his 2 meter radio without a license. He used to be WB6JAC.

Burton has a long history of repeated amateur radio violations going back more than a decade. The FCC initially revoked Burton's ham ticket in 1981, but that didn't keep him off the amateur air waves. A 1984 federal court found him guilty of transmitting on the ham bands without a license . . . and using obscene language.

The obscenity charge was later overturned but the license revocation continued. He was sentenced to a four-year federal prison sentence which was later reduced to six months, to be followed by a five-year probationary period. He served the sentence at the Lompoc (California) federal detention facility; the probation was over in 1989. In 1990, Burton was once again monitored on the 2 meter band and convicted of operating without a license. This time he was ordered to undergo therapy.

Last summer, Burton was again cited for making several illegal unidentified 2 meter ham radio transmissions after the Los Angeles FCC Office tracked his broadcasts to a Redondo Beach address. He pleaded innocent and was ordered to return to federal district court for jury trial last November.

On December 1, 1993, Richard Burton was convicted on all four counts of operating an amateur radio station without a license. This was his third conviction. He could have received up to a two-year prison sentence and a \$10,000 fine.

After the prison sentence, Burton must undergo psychological counseling and perform 500 hours of community service. *Los Angeles Times* writer Bob Pool quoted Burton as saying, "I think I need to get myself another hobby." *TNX W5YI Report*, Vol. 15 Issue #6, March 15 1993.

Fake Distress Calls

As part of a plea bargain arrangement, Jorge Mestre NS3K of Fairfax, Virginia, has surrendered his amateur Extra class license and must dispose of his ham radio equipment within 60 days. Mestre pled guilty to willfully making fabricated 20 meter distress calls last summer on 14.313 MHz. The SOS supposedly involved a sinking ship located in the West Indies. Ham operators notified the Coast Guard and the FCC. The massive search and rescue effort cost the Coast Guard more than \$100,000. Mestre has agreed to make \$50,000 in restitution.

The prank distress calls were traced to Mestre through the efforts of the FCC's long-range direction finding network, computer anal-

ysis of tape recordings, and "signature print" comparison tests on Mestre's equipment, which was later seized on a federal search warrant. He will be sentenced on May 7th and faces six years in prison and a \$250,000 fine. *TNX W5YI Report*, Vol. 15 Issue #6, March 15 1993.

TV Series Coordinated on the Ham Bands—Producers Leased Radios From Commercial Firm

During mid-February, a Fort Worth, Texas, amateur scanning the amateur 420 MHz ham band came across transmissions that didn't sound like ham radio. They sounded like unidentified business communications. He called the FCC and retransmitted the signals over a local repeater so the FCC in Dallas could hear them. An engineer was later dispatched to Fort Worth to investigate. The operation was located through close-in direction finding techniques.

It turned out that Cannon Television, Inc., of Irving, Texas, and a West-Coast-based television crew had rented 36 Motorola P-200 handheld radios to direct operations for "Walker, Texas Ranger"—a television series being produced in downtown Fort Worth, starring actor Chuck Norris. The problem was that the radios were apparently unlicensed and were programmed to operate on 443.0125 MHz and five other nearby frequencies in the 70 cm ham band.

The Dallas FCC Field Office issued a *Notice of Apparent Liability for Forfeiture* (an FCC administrative fine) in the amount of \$8,000 against Cannon Television, Inc., for operating unlicensed radio stations.

The radios were apparently labeled with the proper business band channels but were programmed to operate on the ham bands in between simplex 70 cm frequencies. The television series' producer, Bob Hargrove, said he knew nothing about the legalities of "radio"—only that he routinely rents them all over the United States for shooting on location. "We had someone fly in from Houston that night to reprogram the radios," he said. "Delt Communications (the Houston company that rented out the radios) is also confused as to what went wrong. These same radios were used on two Oliver Stone movies here—and numerous other pictures. No one has had a problem." *TNX W5YI Report*, Vol. 15 Issue #6, March 15 1993.

FCC Issues \$10,500 Fine for Malicious Interference

The FCC has handed a ham a record \$10,500 Notice of Apparent Liability to Monetary Forfeiture. The fine was issued to Richard L. Whiten WB2OTK of Taylors, South Carolina, for what the FCC called "malicious interference to the communications of other ham radio operators." The operators the FCC says Whiten in-

terfered with are Michael Galego KA4MUJ of Ft. Lauderdale, Florida, and Judith Duehring KA1SKV of Maynard, Massachusetts. Galego and Duehring are publicly avowed followers of the anti-service net "Better Amateur Radio Federation," headed up by convicted felon Herbert L. Schoenbohm KV4FZ.

The FCC's Kingsville, Texas, office says it monitored and recorded a conversation on the frequency of 14.314.7 MHz on September 26, 1992. According to the January 19th NAL, Whiten did not dispute making the cited transmissions but did deny that they "constituted willful and malicious interference." Whiten told the FCC that, "if [he] had truly wanted to willfully and maliciously interfere [he] could have done so to such an extent that communications between other amateur radio operators would have been impossible."

But the FCC Engineer-in-Charge Oliver K. Long, who issued the fine, looked at this as a simple case of Whiten interfering with other amateur communications, that Whiten has in writing admitted his guilt, and that he therefore is subject to the administrative penalty as prescribed. The notice says that the base amount of the fine is \$7,000 but that it has been adjusted upward another \$3,500 dollars because of what EIC Long says is Whiten's "repeated violation of rule 97.101(D)."

The FCC gave Whiten 30 days (from January 19) to either pay the fine or file a petition for reduction or non-imposition of the penalty. In a telephone interview on January 24th, WB2OTK told the Amateur Radio Newsline that he has no intention of paying the forfeiture and plans to hire a Washington, DC, attorney who specializes in communications law to fight the matter through the administrative appeals process, and if needed, into the federal court system. *TNX Westlink Report*, Number 643, February 18, 1993.

More Fines for Malicious Interference

The FCC has issued another Notice of Apparent Liability, this time for \$2,000 against William A. Moskowitz KA3HSZ of Plano, Texas.

The FCC's Vero Beach, Florida, office issued the notice on January 14 after having monitored Moskowitz on November 26th of last year. The NAL says that during a 17-minute period, the government observed him changing operating frequency twice in the vicinity of 14.313 MHz, "in order to interfere with ongoing communications."

"The violation was willful," the FCC said.

The public notice also said that the Commission is "treating this as a minor violation." Since Moskowitz is an individual, because of the nature of the violation, and because it is a first offense, the Commission set the fine at \$2,000. The FCC's base forfeiture for malicious interference is \$7,000.

Moskowitz has the usual 30 days to pay the fine or appeal it. *TNX Westlink Report*, Number 643, February 18, 1993; ARRL.

The Hows and Whys of Coaxial Cable

How to select the most appropriate kind for your need.

by Steve Katz WB2WIK/6

Hams have used coaxial cable for transmission lines almost since its invention nearly 50 years ago, but many don't know why or how this trend started. Although much has been written on the subject, I'm frequently startled to hear so much misinformation chatted about on the ham bands, even by old-timers who should know better. Perhaps this article will help newcomers and old-timers alike clear up misconceptions and make more educated decisions regarding this important piece of station apparatus.

Why Coax?

Why do we use coax, and why is most of it 50 ohms nominal impedance?

This is the best question anyone can ask. Before there was coaxial cable, amateurs and professionals alike used primarily open-wire transmission lines, typically in the 300 to 600 ohm nominal impedance range. Sometimes they used no transmission line at all—they just directly fed antennas with a single piece of wire. In the latter arrangement, the connection wire became part of the antenna system itself, and radiated along with the antenna. The drawback to this scheme was that the connecting wire's orientation would play a critical role in antenna performance, and often a high-voltage point would appear right at the antenna connection to the transmitter, creating both RF interference and even possibly fire hazards when the wire would come in proximity to combustible materials.

Open-wire "balanced feeders" helped solve some of these problems. Because the currents in the feeder wires were balanced (assuming a well-balanced load, or antenna), feedline radiation was minimized and the RF field contained to a very small area around the wires. By orienting the feeders perpendicular to the intended antenna field, antenna radiation pattern distortion would also be minimized and antennas could be better optimized. Open-wire "balanced feeders" were also a natural for connecting vacuum-tube push-pull amplifier circuits to balanced antennas without the need for complex matching networks. Tube amplifiers are normally high-impedance devices whose output

impedance is roughly equivalent to the plate voltage divided by the plate current of the output stage. Thus, a tube amplifier with 1,000 volts on the anode, drawing 500 mA anode current (this is a 500 watt stage), would have a plate load impedance of about 2,000 ohms. Matching 2,000 ohms to a 600 ohm open-wire feeder connected to a 600 ohm balanced antenna required only a transformation ratio of 2000:600, or 3.33:1, which was easily achieved by a very simple, low-loss "link output" circuit.

The problem with open-wire lines, and

"Coaxial cable solves a great number of problems and that is why it is used so universally in amateur as well as non-amateur communications systems."

"twin-lead," which is identical to open-wire except that the dielectric (spacer insulation) is a continuous strip of material (such as polyethylene), is that they are adversely affected by conducting objects in close proximity to them. They cannot be taped or otherwise directly attached to metal towers, masts or antenna booms, and even water, snow or ice laying on them dramatically increases their losses. Twin-lead and open-wire feedlines must be carefully insulated and spaced from all surrounding objects and cannot be directly buried beneath the earth. Besides all this, they still radiate to some degree, especially if terminated in any kind of unbalanced load. And, although the current in high-impedance feedline is lower than it would be in lower-impedance (coaxial) cable, making IR (ohmic) losses lower, voltages are much higher, to the point where exposure to living organisms (like people!) can be deadly hazardous. For example, if someone were running the amateur legal-limit power level of 1,500 watts PEP output and using a 600 ohm antenna and feedline, the voltage across the feedline would be 948.68 volts (calculated by the for-

mula: $E = \sqrt{P \times R}$

This is quite a lot of voltage and is considered by all authorities to be extremely hazardous.

Coaxial cable to the rescue! Coaxial cable is self-shielding and, if well-made, does not radiate at all when properly terminated in a matched load. Since the outer conductor (shield) normally operates at ground potential, coax can be secured to all sorts of objects, including tower legs, metal masts and booms, and almost anything else that comes to mind, making its installation extremely uncritical. If the coax has the proper outer jacket material, it may be buried beneath the earth for many years without degradation. Coax is unaffected by the presence of water, snow or ice. Although the nominal impedance of coax is lower than open wire line and it therefore has higher IR (ohmic) loss, its lower impedance allows direct power transfer to low-impedance antennas (a half-wave dipole in free space, for example, looks like 70 ohms) and keeps the voltage across the feedline and antenna connection points to a safer level. A 1,500 watt PEP output transmitter connected to a 50 ohm antenna will have only 273.86 volts across the feedline—still a somewhat hazardous level, but about one-fourth that obtained using a 600 ohm system. Because coaxial cable's working voltage is quite low, its insulating dielectric material may be optimized for minimal loss, rather than maximum insulation resistance.

Why 50 Ohms?

Clearly, coaxial cable solves a great number of problems and that is why it is used so universally in amateur as well as non-amateur communications systems.

"Why is most coaxial cable 50 ohms nominal impedance?"

This can best be answered in two parts: (a) Coax isn't all 50 ohms, but commonly runs from 30 ohms to 90 ohms, and sometimes even a bit higher when called for. Impedance selection is very application-dependent. (b) 50 ohms represents an excellent compromise between the lowest possible transmission

loss, which occurs at 70 ohms nominal, and the highest possible power handling capability, which occurs at 30 ohms nominal. Because of these factors, 50 ohms was settled on as the best all-around impedance for the widest variety of applications. To this day, 70 ohm cable is used almost exclusively in receive-only applications where no power transmission is required (such as cable TV systems).

Cable Specs

If 50 ohm coax is the best thing to use, I guess I should buy a big roll of RG58/U and use it everywhere. Isn't that right?

Yes and no. RG58/U might be great stuff, but again, most choices in life are application-driven and one needs to consider the specific use before making an intelligent cable selection.

First of all, what do the "RG" numbers mean? Well, these indicate that the cable is *registered* (simply a matter of someone spending the money and filling out a few forms). Cables which are truly RG-XX-/U are also "mil-qualified," which means they are certified for lot compliance with MIL-C-17D, the general military specification for wire and cable, and manufactured in a qualified facility. The two- or three-digit number after the "RG" prefix means absolutely nothing by itself: You need to refer to MIL-C-17D to see exactly what the cable designator means. The numbers are arbitrarily assigned in numerical order, from 1 to infinity, and only tend to indicate the age of the product's registration. For example, RG8/U is a much older product than RG213/U, which is essentially identical except that RG213/U is a *QPL* (MIL-C-17D qualified) product, while the older RG8/U no longer is, having been replaced by the newer part number. Many amateur coaxial products are not mil-qualified at all, but might still be imprinted and sold as "RG" products. Usually, if these are identical to mil-spec cables but are simply not qualified, they will be labeled with the word "TYPE" after the part number: For example, Belden 9913 is "RG8 TYPE" cable but is not RG8/U. Other non-qualified products might simply leave off the "U" suffix, such as "RG8X" or "RG8M" mini-8 cable. Admittedly, it's all a bit confusing.

How to Choose

Since most of us will be using 50 ohm cables in our stations, the most important parameters to consider in making product choices include: (a) transmission loss; (b) power handling capability; (c) flexibility; (d) availability of standard and reasonably-priced connectors; and (e) resistance to weathering and ultraviolet (UV) exposure. These parameters vary in importance and not necessarily in the order I've listed. Again, the selection is and should be application-dependent. Oh, yes—I've almost forgotten the most important parameter for many hams: **COST!**

In general (but not always), the larger diameter the cable is, the lower its loss will be

at any given frequency. This is because the leading contributor to transmission loss is the ohmic resistance of the conductors, which are usually copper, and the larger the cross-section the conductors have, the lower their resistance will be. But if loss were based on conductor size and ohmic (DC) resistance alone, coaxial cable would have the same loss for a given length at all operating frequencies, from DC to microwaves. That is *not* the case.

There are two other factors that enter into the RF loss equation (and they do not apply to DC circuits). One is a property called "skin effect," which assumes that AC (and RF) currents will flow only in the outermost surface of any conductor and therefore conductors could be hollow (with no center core at all) and be just as effective as solid conductors for any given diameter. The other is dielectric (the spacing insulation between the center and outer conductor) loss, which increases directly with operating frequency for most commonly used dielectric materials. The "skin depth" of a conductor becomes more and more shallow as the RF fre-

"It pays to select coaxial cable which has commonly-available, reasonably-priced connectors that will fit."

quency is increased, meaning that a more and more shallow region of the conductor is used as we work our way up the spectrum. This means that a given conductor will have loss that increases with frequency, as less and less of the conductor is actually used.

There is a third factor that applies mostly to *flexible* coaxial cables (the most-used kinds in ham stations), and that is radiation loss, which also increases directly with frequency as the outer conductor, which is made of braided materials to add flexibility, becomes a less effective shield for containment of RF energy. Solid outer-conductor cables (semi-rigid, rigid, "hardline," etc.) typically don't suffer radiation losses.

The bigger the cable is in diameter, the more power it can usually handle, since the conductors will have less loss and thus dissipate less power (generating less heat) and the insulating materials tend to be thicker, too, sustaining higher operating voltages. An exception to this general rule are the Teflon dielectric cables, which have great power handling ability even when small in overall diameter. This is because Teflon can withstand much greater heating than normally-used insulating materials, like polyethylene, and it has a higher dielectric withstanding voltage for a given thickness. This is *not* to say that Teflon cables are superior to standard polyethylene ones—they are not, except as regarding power handling for a given diameter. In general, Teflon cables are actually *inferior* to standard polyethylene-insulated coax in almost all other respects be-

cause Teflon has a high dielectric constant, creating the need for smaller center conductor size (for a given nominal impedance) and increasing dielectric losses. An example of Teflon coax is RG400/U, which is about the same size as RG58/U but will withstand more than 10 times the power; however, RG400/U actually has *more* transmission loss than standard RG58/U and costs about 10 times as much!

Throughout the HF spectrum, hams use "UHF" or "PL259" type connectors almost exclusively because commercially-made gear is already fitted with their mating receptacles (SO239) and they are good, high-power, inexpensive fittings that are very useful through 144 MHz or so. However, on 220 MHz and above, the connector of choice is the Type "N," which has a variety of military designators, mostly UG21D/U. The Type "N" connector surely costs more than the "UHF" PL259 type, but is actually easier to install and is a far superior connector throughout the VHF/UHF/SHF spectrum. In fact, some Type "N" fittings work well through 12 GHz (12,000 MHz)! For smaller cables, both PL259's with appropriate "reducers" (type UG175/U and UG176/U for RG58/U and RG8X types), Type "N" and "BNCs" are commonly used. BNCs are very good fittings through the UHF and SHF spectrum and, when properly installed, have no measurable loss at 1 GHz. However, because of their mechanical frailty they are best used with small-diameter cables like RG58/U, RG174/U and so forth.

In any case, it pays to select coaxial cable which has commonly-available, reasonably-priced connectors that will fit, or you may find yourself with \$5 worth of cable that will require \$200 worth of connectors to attach to anything. The "standard" ham coaxial lines (RG58, RG8, RG213, even RG217 and RG17 for those with the budget and need for giant-sized cables) all have readily-available and reasonably-priced fittings. Probably the only caveats in the market are "surplus" cables which cannot be readily identified and "hardline" cables, which do require special connectors that can sometimes cost a small fortune.

Beware of double-shielded coaxial cables! These are often found on the surplus market and, while they might be wonderful in many respects, they can be difficult to use, to flex, and to find connectors which fit. For example, the double-shielded version of RG213/U is RG214/U. These two cables have exactly the same electrical properties, the same transmission loss, and so forth, but the double-shielded type will *not* fit a conventional connector which is intended for single-shielded cable. Why would anyone want double-shielded cable? For very specific and demanding applications, where a few dB of additional shielding is very important. Connections within full-duplex repeater systems come to mind as a good application. If you don't own a repeater, there's no reason I can think of to use double-shielded cable. It's generally more trouble than it's worth.

Specific Questions

After contemplating all of this confusing information, what in the world should I use to feed my 40 meter dipole?

Great question! That's getting down to specifics. Unless you intend to run the legal power limit (1500 watts PEP output), I'd usually recommend RG58C/U (for runs up to 50' long and power levels below 400 watts PEP) or RG8X (for runs up to 150' long and power levels below 1000 watts PEP). These are both very flexible, lightweight cables which will exhibit very low loss on 40 meters in the lengths I've specified, and their only restriction will be power handling. For legal-limit power, I'd recommend RG213/U, which is heavier and less flexible, but will withstand 1,500 watts all day long.

What about feeding my 2 meter beam?

Another great, specific question. The only question I'd ask in reply is, "How long will your feedline need to be?"

For lengths less than 50 feet, RG8X is a good, general-purpose cable for 2 meter use. A 50-foot run will have about 2 dB loss, which is not too much for most applications (like working FM repeaters and such), but might be excessive for demanding applications like SSB/CW weak-signal work where every dB counts. For lengths up to about 100 feet, RG213/U is a great choice. It will lose about 2.4 dB or so in a 100' run. For lengths beyond 100 feet, or for more demanding applications, I'd recommend Belden 9913, which is the same o.d. (outside diameter) as RG213/U but has somewhat lower loss, about 1.3 dB per 100 feet at 144 MHz. The drawback to the 9913 is that it is far less flexible than RG213/U and does not fit a standard Type "N" connector; however, special connectors for 9913 are available and don't cost much more than the standard ones. For very long runs, or highly demanding applications like EME (moonbounce), where every tenth of a dB starts to count) or full-duplex repeater installations, 1/2" or larger "hardline" or Helix is most commonly used.

I'd like to use a single feedline to connect my 146, 222 and 440 MHz FM antennas at home, using a "duplexer" at each end of the line to separate the signals. Any problems with that? What should I use?

There's no problem doing this, as long as you use high-quality "duplexers" (I'd prefer to call them signal-splitters, which is what they really are) on both ends, and remember to make the topside one, which will be exposed to weather, very waterproof. There are some multiband signal-splitters on the market which have almost immeasurably low loss (less than 0.5 dB) and will handle 150 watts or so. Since you intend to use the coax on 440 MHz, where losses will be the highest, I'd recommend RG213/U for short runs up to 50 feet or so, then Belden 9913 up to 100 feet, then commercial "hardline" or Helix for runs longer than 100 feet. Bear in mind that the "hardline" types cannot take repeated flexing, are quite inflexible to be-

gin with, and require specialized, costly connectors. But properly used, it's great stuff.

I have a 10-15-20 meter triband beam on a 70-foot tower located 150 feet behind my house. What do you recommend for coax to feed this system?

I'd probably recommend RG217/U or RG17/U in this case, and I'd bury it underground to get to the base of the tower. It will have minimal loss and is very high quality cable. Connectors are readily available (although they have a larger back end than connectors for RG8-sized cables and are not interchangeable), at least for Type N, and adapters can be used to mate with UHF fittings if necessary. Of course, you could save a lot of money by using standard RG213/U, but since you'll need nearly 250 feet of it, this stuff will begin to get lossy at 28 MHz. It's a matter of balancing your appetite for performance against your budget and trying to make the most educated decision possible.

"Properly-installed coaxial connectors have losses too low to measure if they are used in the spectrum for which they were intended."

I've heard that coax connectors all have loss, and every time you use one, you're giving up a dB or so. Is this true?

Not at all! Where in the world did you hear this gibberish? While everything has some loss in this imperfect world, properly-installed coaxial connectors have losses too low to measure, even with the world's most sophisticated laboratory equipment, if they are used in the spectrum for which they were intended.

A "UHF" connector, say type PL259ST, which implies a silver-plated connector with a Teflon dielectric (the best kind to use because they solder so easily and resist soldering heat so well), used at 28 MHz will have less than 0.01 dB insertion loss when mated to an equivalent receptacle. Similarly, a UG21D/U Type "N" connector, properly installed and mated to its equivalent receptacle, will exhibit less than 0.05 dB loss at 500 MHz! This is a whale of a lot less than 1 dB loss. The problem is, many amateurs don't know how to install connectors properly, and probably do end up with more loss than there should be. But 1 dB is an awful lot to lose, especially at the lower frequencies, where simply twisting the coax conductors together in a "mid-air" splice and using no connectors at all will usually result in far less than 1 dB loss.

Probably the worst misapplication of RF connectors is when hams try to use "UHF" PL259 types at 440 MHz. Most of them don't work very well at this frequency, and losses may be as high as 0.5 dB per connector or so if you're not careful. At 440 MHz and above stick with the time-proven, con-

stant-impedance Type N fittings.

My 220 MHz "mag mount" whip antenna came with RG174/U coax installed, about 10 feet of it. Is this lossy? Should I replace it?

At 222 MHz, 10 feet of RG174/U will lose about 1.3 dB or so. Replacing it with an identical length of RG8X will only lose 0.5 dB, so you'd pick up about 0.8 dB by making the change.

What about the coax sold by Radio Shack and similar retail outlets? Is it any good?

It can be, but it might not be. I don't mean to disparage Radio Shack or anyone else, but the problem with commercial, non-military cables is the lack of consistent quality. Since their cables are manufactured in non-qualified facilities and each lot does not undergo the rigors of considerable Quality Conformance Inspections, many times these products are less than desirable, especially for long-term installations. I'd not hesitate to use their stuff for patch cables around the shack, or for mobile installations and other non-critical applications where the cable can easily be replaced. But for more demanding applications or installations where replacement might be very difficult, I'd stick with the real mil-spec products, or at least try to find the highest quality commercial products available. Shop around a bit, looking not only at the price, but also at the product itself. Is the braid coverage very good (at least 95% of the dielectric should be covered by the braid, with no visible "holes" between the strands)? Is the outer jacket "UV stabilized" (that is, will it withstand continued ultraviolet radiation from the sun without contaminating the cable)? Is the run you intend to use free of splices under the jacket (usually visible as a small bump in the cable diameter)? If everything looks great, use it! If not, look elsewhere.

What about "foam" cables versus "non-foam"? What's the difference?

"Foam" cables use this term to refer to the dielectric material; it is cellular polyethylene, which looks a bit like foam rubber, and is softer and spongier than solid-dielectrics. The "foam" stuff is usually very white in color (although it needn't be) and you can permanently indent it with your fingernail. Foam cables tend to be a bit more flexible than those with solid dielectrics, and their transmission losses will be slightly lower for a given cable type and diameter. However, there are drawbacks. The cellular foam melts easily at a relatively low temperature, and once melted, it is permanently damaged. Because of this, foam cables are really intended for "crimp-on" connectors, not the solder-on kind, which obviously will expose the dielectric to very high temperatures during the soldering operation. Also, the nature of the foam dielectric is to absorb water easily, making the cable quicker to contaminate if the jacket is pierced or if a terminating connector leaks a bit of water. Solid dielectric cables are more robust and will withstand soldering heat better, and are also less prone to the absorption of moisture. Because

of the operating temperature restrictions, no "foam" cable is mil-qualified. However, throughout this article I have recommended RG8X for some applications, and RG8X is a "foam" cable type. Use it carefully.

Why does "foam" cable have less loss?

Two reasons. One, the cellular polyethylene has a lower dielectric constant than solid, so dielectric losses are somewhat lower. Two, because of this same fact, the center conductor will be larger in diameter (for the same outside conductor diameter) to maintain 50 ohms impedance. (The nominal impedance is a function of the inner conductor diameter as related to the outer conductor diameter, and the constant of the dielectric used between them.) With a slightly larger diameter center conductor, ohmic losses (and skin-effect losses at RF) will be somewhat reduced, without impacting the overall diameter of the cable. Whether or not you'll really notice the difference in loss will depend on the length of cable you use.

What about "9913"? Is it as good as they say it is?

"9913" is excellent with respect to transmission loss and power handling ability. It is often called "poor man's hardline" because it might be nearly as good as hardline, while costing far less. "9913" is really just an extension of "foam" dielectric cable. Instead of using cellular polyethylene, Belden (the inventor of 9913) uses a thin spiral of polyethylene dielectric material as a spacer to hold the center conductor in place, and a lot of the dielectric is really the air between the spiral turns. Picture the dielectric in 9913 as a long spring, with lots of coils and air in the spaces between. As a result, the dielectric constant is even lower than in "foam" cables, the center conductor is even larger and has less resistance, and everybody is happy as a clam. Of course, braided outer conductors for 9913 would never work, as there'd be nothing rigid enough to hold the cable together. So the manufacturers use a very thin wall of polyethylene, covered with aluminum foil to make the outer coaxial conductor. Since you can't really solder to aluminum foil, they cover that with some tinned copper braid material. The braid serves no particular purpose other than giving you something to solder to (for a PL259) or clamp to (for a type N).

The problem (and there's always a problem with anything that seems too perfect) is that 9913 is far less flexible than conventional cables, will not withstand repeated bending (due mostly to that big, fat, solid center conductor and the fragile aluminum shield), is easily contaminated by the very first droplet of water that might enter in past a connector, and is too fragile to rigidly clamp to a tower leg or other solid support. If you use proper precautions, 9913 is great stuff. If you don't you'll wind up replacing it frequently. Belden will be glad to provide you with an applications note on how to use 9913 correctly. It was really intended for crimp-type connectors, not solder-on ones, so be extra careful.

I've heard that a solid center conductor in coax is better than a stranded one. Is that true? If so, why?

No, this really isn't true. Since the RF currents flow only on the perimeter of any conductor, only the outside diameter of the center conductor is of consequence in determining attenuation. (The same is true for the inside diameter of the outer conductor, because that's where the current flows there.) To maintain a constant and desired impedance, the ratio of the o.d. of the inner conductor to the i.d. of the outer conductor must be a fixed, predetermined quantity for any given dielectric material. It doesn't really matter if the inner conductor is solid or stranded, as long as its o.d. (outside diameter) is correct to maintain the desired nominal impedance. Solid conductors are generally used in cables that will not be exposed to repeated flexing, like 9913 and hardline, while stranded center conductors are used in cables intended for flexing and smaller-radius bends because the stranded conductors are far more flexible. For this reason, I'd always recommend cables with a stranded

"In amateur installations, the factors that detract from the operating life of coaxial cable are typically abrasion, moisture, and UV radiation."

center conductor for routing in tight spaces, around rotators, in mobile installations, as "patch" cables for use around the shack and in other applications where flexibility is required. For example, rather than using RG58/U or RG58A/U, I'd recommend RG58C/U in almost all applications for small-diameter cable. The RG58C/U has a stranded center conductor while RG58/U and RG58A/U do not. A perfect example of the resilience of the stranded conductor cable is when it is used to attach a mobile "mag mount" antenna, where the car door may be repeatedly slammed against the cable. RG58/U might withstand this abuse only a few times before it finally breaks, while RG58C/U will withstand similar abuse hundreds of times because it is so much more flexible. (It's still not a great idea to slam a car door against the coax, but I know it's done, and will be done for years to come.)

I've heard that coax's ability to withstand UV radiation has something to do with the cable's suffix designator, like A/U, B/U, C/U, etc. What's the story on this?

Cables will last nearly forever if they're never exposed to excessive temperatures (hot or cold), weather, or ultraviolet radiation. Unfortunately, that means we really can't use them. In the real world, cables are exposed to all these things which impact operating life. In amateur installations, the factors that detract from the operating life of coaxial cable are typically abrasion, moisture, and UV radiation. UV radiation, which

gives us such great tans in the summer, can cause the plasticizers in the jacket materials of coax to "migrate" and flow through the braid and into the dielectric material. When this happens, the dielectric becomes contaminated and the cable's attenuation increases. To avoid this occurrence, manufacturers—especially mil-qualified ones—began using "UV stabilized" jacket materials (usually polyvinylchloride, or "PVC") which will withstand UV radiation under normal conditions without migration. Unless you intend to use all your coax indoors, where it will never be exposed to the sun's rays, it certainly pays to use coax cable that has a "UV stabilized" jacket material. This material is commonly called "Type IIA," an industry buzz-word for the enhanced properties discussed here. Old-fashioned RG8/U was not Type IIA; RG8A/U supposedly was, and replaced RG8/U on the military QPL (Qualified Products List) for MIL-C-17D years ago. Because of the confusion created by two such similar part numbers, RG8/U and A/U were dropped from the QPL entirely and have been replaced with RG213/U, which should automatically have a UV stabilized jacket, if it is real mil-spec coax. A similar story exists for RG58/U: The old number was not Type IIA, but RG58A/U, B/U and C/U. This is a bit confusing, so it pays when purchasing cable to find out for sure if the product has a Type IIA jacket material. All the newer mil-spec products do, but many commercial products don't. RG8X, which is a purely commercial product (and is not mil-spec in any form) is made by a variety of manufacturers using different materials; some are UV stable and some are not. RG8X and other commercial cables are often available with a white-colored jacket material, which may be desirable for those wishing to "hide" the coax against the side of a light-colored building or interior walls. Whether the white jacket material is UV stable or not, it will reflect the sun's rays better than a black jacket and run cooler and absorb less UV radiation than black-jacketed coax. The white-colored stuff is often used in marine applications, where UV exposure is the norm.

I used RG58/U to feed my 2 meter antenna for years, and its VSWR was always 1.2:1. I just replaced the feedline with brand-new RG213/U of the same length and now the antenna VSWR measures almost 2:1. Why is the new coax so bad?

Congratulations! You've actually improved your whole system by a large factor, and your new VSWR measurement is far more accurate. You're obviously measuring the SWR down at the rig, and not up at the antenna feed point, which is where it *should* be measured. Since VSWR is a ratio of feedline to load impedance (not rig to antenna!), a "flat" (1:1) SWR will only exist when the antenna impedance is exactly the same as the feedline's. If there's any mismatch at all, some reflected power will result. When you used RG58/U, a large amount of that reflected power was absorbed by the coax because

it had lots of loss. The reflected power just created some cable heating and never made it down to your VSWR bridge at the "rig" end of the line. Now that you're using less lossy cable, more of the reflected power is actually being conducted back to your bridge, and your rig, and less is being absorbed by the coax. This is a very normal condition. The new coax isn't "bad," it is probably far better than the old coax was. If you take the trouble to measure VSWR right at the antenna itself, you should find it will be the same with any 50 ohm feedline you connect to it. The best thing to do is re-tune the antenna, using a bridge connected directly to it (up on the roof, tower, or whatever) and try to optimize this match to 1:1 at the frequency of interest. If you can do this, there will be no standing waves on the feedline and the SWR will measure the same at the antenna, the rig, or anywhere in between. By the way, *all* the reflected power will eventually be absorbed by the feedline regardless of how much there is. This is an interesting subject on which much has been written, and there's insufficient space to cover it completely here.

How can I keep water out of my feedline?

A few simple precautions will prevent moisture from entering coax in most situations. The first is, when measuring, cutting and handling the cable, be careful not to create abrasion of the jacket. While some cables are nearly impervious to rough handling (like the ITT Impervion cables) because they are "self-healing," most are really quite fragile. Don't drag your coax across the pavement or roofing materials, and don't yank it through the legs of your tower. Treat it as though it were expensive silk fabric that could be easily damaged—because it can.

The second thing is, install the exposed connector (the one that attaches to your antenna) in a precise, proper and professional manner. Make sure the jacket ends *inside* the RF connector, and that no braid is exposed after the connector is installed. Then, weatherproof the connector as well as possible. "Coax Seal" weatherproof putty works well, if its directions are followed carefully. This stuff molds itself around the connector and the coax near the connector and is very weather resistant. Lacking "Coax Seal" or something similar, you can try spraying the connector and a few inches down the coax with Krylon "Klar Kote", then wrapping with overlapping layers of high-quality vinyl tape like 3M "Scotch 88" electrical tape, then spraying over the tape with another coating of "Klear Kote." It is not impossible to make an exposed RF connector totally weather resistant, it just takes some practice and some patience. Then, *don't* pull the coax straight away from the antenna connector and run it down a mast, boom or tower leg: Make a "drainage loop" in the coax, maybe 6" or so in diameter, by forming a 360-degree coil in the coax before routing toward the shack. Make this "loop" very close to the coax connector, preferably an inch or two away. Tape the loop in place so it will hold

its form, and then carefully route the coax towards the shack, never pulling hard on it. When installing the "drainage loop," make sure the loop itself is all *below* the antenna connector, with the turn of the loop facing down towards the ground. This will help prevent any moisture that happens to enter the connector from "wicking" down the coax and contaminating the whole length, so if you do have a water problem in the future it will be confined to the first few inches near the antenna connector. If this *does* happen, at least you'll have enough coax left up there to cut off the old connector and the few inches of contaminated coax, install a new connector and reattach it to the antenna. You won't have to replace the whole line.

How can I tell if my surplus coax is any good? I got a real bargain on it, but am afraid to use it until I test it somehow.

First, cut a few inches off each end of the coax to get a "fresh end" exposed. Then, cut away the outer jacket to expose the braid. Is the braid shiny? (It may be pure copper, tinned copper or silver-plated copper, but in all cases it should have a shiny, new finish

"When measuring, cutting and handling the cable, be careful not to create abrasion of the jacket."

and not be discolored, green or black.) Now, pull back the braid and look at the dielectric material. Does it have a new-looking, consistent color? (It may be white, off-white, translucent or nearly any color, but it should not be stained or discolored by the braid oxides or jacket plasticizers.) Now, cut back some of the dielectric and look at the center conductor. Is it shiny and new looking? (It may be pure copper, copper-plated, tinned, or silver-plated, but it should look shiny and new and not be oxidized.) If the answer to all these questions is, "Yes," then the cable is probably fine. But you may want to make an electrical measurement just to be sure.

If you have a good VSWR bridge or directional coupler of high quality, you can make two simple measurements. First, install connectors on both ends of the coaxial line. Next, connect your VSWR bridge at the transmitter end of the line with a short "jumper" and connect the TX end of the bridge to your transmitter. Then, install a "dead short" circuit across the far-end connector, which would normally go to the antenna. You can make a good short circuit that will be effective up to 144 MHz or so by using a piece of #12 copper wire and soldering it between the center and outer conductors of a mating receptacle. Keep the wire very short, under one-fourth of an inch long. (At frequencies above 144 MHz, a commercial short-circuit RF termination, usually type N, will work better. These are available inexpensively via surplus outlets.)

Now transmit, using the lowest possible power to obtain a reasonable reading on your VSWR bridge or wattmeter. Switch the bridge back and forth between forward and reflected ranges. The VSWR should read infinity, or close to it: Forward and reflected power will both be the same if the cable has minimal loss. The *difference* between forward and reflected power indications is the power lost in the cable, but remember this will be the power lost by the signal traveling both up and down the cable (to the short-circuit termination and back to the transmitter), so the attenuation in just *one* direction is one-half the difference between forward and reflected power readings.

For example, if you transmit with 5 watts of power and measure a reflected power of 2.5 watts, a total of 3 dB is lost by the cable when the signal travels to the termination and back again. The single-trip loss (signal traveling from transmitter to termination only) will be one-half this amount, or 1.5 dB. The dB loss is calculated as follows:

$$\text{Attenuation (dB)} = 10 \log_{10} \frac{P_1}{P_2}$$

Where P1 is the transmitter forward power (5W), P2 is the reflected power (2.5 W) and the attenuation is for a "round-trip" in the cable; the one-way attenuation, which is a more relevant parameter, is one-half this amount.

If you'd prefer not to intentionally transmit into a short-circuit (and some solid-state rigs won't let you, due to their internal VSWR protection circuitry), you can make a similar analysis by taking a few extra steps and using a good 50 ohm "dummy" load, as follows:

Connect your wattmeter to your transmitter using a short "patch" cable, and terminate the far end of the coax line with a high-quality 50 ohm (non-reactive) dummy load. Connect the TX end of the coax to the antenna port of the wattmeter, and transmit with as much power as possible to achieve a high-scale reading on the meter. Read this indication and write it down. Then, disconnect the wattmeter from the transmitter, connect the coax directly to the transmitter, and re-install the wattmeter at the far end of the coax, right next to the dummy load. Transmit again using the same power as before and record this reading. Subtract the lower reading (which should be the second one) from the higher reading, and calculate the one-way cable loss using the same attenuation formula as before (10 times the log of the power ratio). Using this method should yield exactly the same results as using the "return loss" method described earlier.

In the example set forth, where the cable has 1.5 dB loss, you might measure 25 watts at the transmitter and 17.7 watts at the far end of the line. The loss of 7.3 watts in this case is exactly 1.5 dB.

I tend to use the "return loss" method, with a very high-quality short-circuit termination, for most of my cable evaluations because it is simpler, and does not require in-

stalling the meter at each end of the line. But I also usually use a signal generator running very low power (like 10 milliwatts, which is +10 dBm) and a very good directional coupler in my system, so I'm not relying on transmitters and high-powered wattmeters. Attenuation in any cable is a fixed number at a given test frequency and will not vary with power applied, so my system yields very accurate results and is a quick way to check lots of cable.

As discussed throughout this article, there is more to know about coaxial cable than just how much loss it has. Its overall quality of materials and construction, resistance to the effects of weathering and UV radiation, flexibility, ease of use and other factors can be equally, if not more, important. Yet, attenuation (or loss) is probably the most important criteria for the majority of users and applications, especially if the load cannot, for some reason, be matched to the line and a high SWR results.

One last note on this subject: Do not be misled into thinking that SWR, or the match between your feedline and its terminating load, is any indication of *efficiency*. The two parameters—SWR and efficiency—are mutually exclusive. It can be proven that if your feedline loss is *zero*, it won't matter what the SWR is because 100% of all the power generated by your transmitter will be coupled to the antenna and *no* power will be lost.

Table 1. Coaxial Cable Data

Cable Type	Z ₀ Ohms	o.d. (in.V.F.)	Attenuation dB/100'					Dielectric
			50	144	222	440	1260	
RG58C/U	52	.195 66%	3.1	5.7	7.5	11	L9	PE

9913 Belden*	50	.405 84%	0.64	1.3	1.8	2.8	5.4	Air/PE
RG331/U*	50	.500 78%	0.60	1.1	1.5	2.4	4.0	FPE
RG17/U	52	.870 66%	0.50	1.0	1.3	2.3	4.4	PE
RG332/U*	50	.875 78%	0.35	0.65	0.80	1.3	2.5	FPE

Notes:

Cables denoted by an asterisk (*) are commercial cables and not qualified to any military specification.

V.F. = Velocity Factor of propagation. Not an important parameter unless cable is used in a tuned circuit, stub, trap or filter application or used as a precision phasing line.

Attenuation figures are plotted for 50 MHz through 1260 MHz only, as most cables have very little loss per 100 feet at frequencies below 30 MHz.

Dielectric type codes: PE = Polyethylene; TFE = Teflon; FPE = foam (cellular) polyethylene; Air/PE = helical dielectric of polyethylene and air.

Data taken by WB2WIK using 1000' lengths of each cable listed, measuring actual loss by "return loss" method, and dividing measured loss by 10 to calculate loss per 100 feet.

RG331/U and RG332/U are standard aluminum outer conductor "hardline" types which require specialized connectors. Used mostly for reference.

In my next article, I'll discuss the proper installation of coaxial connectors. To whet your appetite, I'll state now that *no* coaxial

connector will take more than 90 seconds to install exactly right if you're armed with the proper tools and knowledge. **73**

AUTO-ID AUTOMATIC MESSAGE BROADCASTER

The **AUTO-ID** is a solid state digital voice recorder that was developed especially for 2 way radios. It simply plugs in between the radio and its microphone. With the use of your radio microphone, you can record up to 5 separate messages that can be played on the air by pressing one of the 5 message buttons. The **AUTO-ID** also has a built-in timer that monitors your PTT (push to talk) activity. Record your station identification, and thereafter any time you are on the

air, the **AUTO-ID** will broadcast your ID message for you. The **AUTO-ID**'s message #1 timer can be set for intervals of 3 or 9 minutes or it may be set to broadcast your message

every time you use your PTT. With the use of the **AUTO-ID**'s built in speaker, you can monitor the message that the **AUTO-ID** is broadcasting, regardless of whether the selected message was broadcasted automatically or manually.

The **AUTO-ID** comes with plugs for an Alinco or Kenwood mobile amateur radio. There are accessories available to interface the **AUTO-ID** to most other types of radios.

FEATURES

- 12VDC power jack.
- Microphone patch cord (INCLUDED).
- 110VAC adapter (INCLUDED).
- Fully wired and tested, just plug it in.
- No soldering required.
- Built in local speaker.
- Adjustable speaker volume.
- Adjustable microphone level.
- Adjustable message broadcast time. (Message "1" only)
- Connects directly in line between radio and microphone.
- Pre-wired for Alinco and Kenwood Mobile radios.
- Power, Record and Play LED indicators.
- TX ready LED indicator.
- Timer enable/disable switch.
- All solid state construction.
- Up to 5 separate messages can be played individually.
- 32 seconds of total digital audio storage time.
- Simple to use.
- 1 year limited warranty.

An *Almost* Everything Amplifier

Change from 7 MHz to 225 MHz with no bandswitching or tuning!

by John Cunningham AA4AW

There are times when you need more power to get into a repeater or to be heard across the country. People who operate handhelds or QRP sometimes find that they have a hard time communicating with such limited power at their disposal. However, buying an amplifier for 10 meters, another for 6 meters, another for 2 meters, and still another for 1.25 meters can get expensive. Wouldn't it be nice to have an amplifier that took care of all these bands?

The amplifier described here meets these requirements. It is broadbanded from 7 to 225 MHz—the range of 10 amateur bands (40, 30, 20, 17, 15, 12, 10, 6, 2, and 1.25 meters). It will operate on CW, SSB, AM, and FM—or any other mode that is used on these frequencies. It can be fed with an input of 1/10 to 24 watts (though there is not much gain above 12 watts input) and can deliver an output of more than 200 watts. It can be operated over a voltage range of 12 to 28 volts.

Field-effect transistors are more immune to damage from high SWR and thermal runaway than bipolar transistors. They also have higher gain, greater efficiency, and lower noise. They can be operated over a greater voltage and power range than bipolar transistors.

The MRF175GV is a Gemini twin which means it is two balanced transistors in one package. The amplifier designed here will not work unless the transistors are balanced.

Field-effect transistors have a few draw-

backs. They are more prone to static damage, and care must be exercised during handling until they are soldered onto the board. They easily go into oscillation, owing to their high gain. Be careful not to drive them too hard and destroy the gates. If there is a chance of this happening a limiting circuit should be installed at the input of the amplifier.

Collecting the Parts

The MRF175GV field-effect transistor can be ordered from RF Parts (telephone: 1-800-737-2787 or 619-744-0700). The transformers, chip caps, and copper heat spreader are available from Communication Concepts, Inc. (hereafter referred to as CCI) at 508 Millstone Drive, Xenia, Ohio 45385 (telephone: 513-426-8600). Experimenters who plan to use a similar design in future projects should purchase the coax needed to make the transformers instead of buying them fully assembled. CCI will not send less than five feet of the coax in any one shipment. Five feet is enough to build five output transformers and almost 10 input transformers. However, once you go this route you must also buy the ferrite beads that accompany the transformers.

The total cost of this project is about \$362, but that doesn't seem so high when you consider that many of the parts must be ordered in more quantity than is necessary for this project, and the excess can be used on future ventures. The copper heat spreader, for instance, can be cut into three pieces and used

in two other projects. Also remember that a high percentage of the cost is in the transistor at \$154. If this sounds expensive, consider that to get 200 watts from commercially-built amplifiers you usually pay more than \$200, and most of these amplifiers are single-band! Multiply \$200 by the 10 amateur bands that this amplifier covers and you get a whopping \$2,000—far more than the cost of this amplifier. Maybe you will not work all 10 of the amateur bands which this amplifier will handle, but if you are an experimenter you probably will.

Construction

I used a Radio Shack 276-1499 circuit board and cut it to the proper size. A single Radio Shack card will build two of these amplifiers. This design consists of two separate cards: one for the input and one for the output. The cards are cut to a size that will enable them to fit into a Radio Shack aluminum box (no. 270-238) 5-1/4" x 3" x 2-1/8". The output card should be cut to 2-3/4" x 2-11/16". The size of the input card should be 2-11/16" x 1-3/4". (Custom pre-etched circuit boards for this project are available for \$7 a set plus \$1.50 S & H from FAR Circuits, 18N640 Field Court, Dundee IL 60118.)

A copper heat spreader is cut to a size that will allow it to fit into the box and enable the lid of the box to fit over it: 5-1/16" x 2-11/16" will make the proper fit.

You will need to drill holes into the boards, box, heat spreader, and heat sink to mount the hardware that holds these devices together. These holes must be lined up with the holes drilled for the circuit board, except that the rectangular holes will not be made in the heat spreader, box, or heat sink. You will also need to drill holes for the bolts that hold the transistor in place. See Figures 2 and 6.

In addition, you will need to make inserts in the circuit boards and the heat spreader (See Figures 2, and 6). I used a grindstone to make the inserts. Without the inserts, the connectors will not fit on the sides of the box.

Holes should be drilled on the output board to bond the ground on the component side of the board. (See Figure 2.) Once the holes are drilled, a lead from a resistor or other component can be placed in the holes and soldered to both sides of the board.

Photo A. The multi-octave amplifier. Photo by John Cunningham AA4AW.

I used Radio Shack 276-1435 etchant, according to the instructions printed on the etchant bottle. Only one side of the board will be etched, except for a little on the lower side of the output board where the power transistor will be. See Figure 2. I drew the pattern with a felt pencil which left the copper to be etched, except for a little on the lower side of the output board where the power transistor will be. Sec Figure 2. I drew the pattern with a felt pencil which left the copper to be etched, except for a little on the lower side of the output board where the power transistor will be. The unetched copper was further protected by duct tape. All components are located and soldered on one side of the board, similar to a ground-plane configuration—the difference being that some etching is done. This design makes for improved grounding and ease of troubleshooting, repair, and modification.

Once the circuit boards are etched, components can be soldered in place. The component layout is not critical, except that capacitors C5 and C6 must be soldered before transformers T1 and T2 are put on the boards. I recommend that you don't place these transformers on the boards until the boards are bolted inside the box and the ferrite beads are put in place. Otherwise, the parts placement is according to Figure 3. I recommend using only chip caps because the leads from other types of capacitors may pick up stray RF and make the amplifier inoperable.

The most difficult part is assembling the transformers. If you order from CCI specify that you want a low-impedance input transformer and a high-impedance output transformer with a 1:9 ratio. CCI does not sell low-impedance input transformers with a 4:1 ratio as called for in this design, but you can order a 9:1 impedance input transformer and convert it to a 4:1 transformer by removing one of the windings. Otherwise, assemble the transformers according to Figures 3 and 4. If you order the coax to build the transformers yourself, specify that you want both input and output coax; they are not the same.

For use at frequencies below 100 MHz, ferrite beads must be put on the input and output transformers to control parasitic oscillations, thereby increasing stability. See Photo A and Figure 4. These oscillations can get so bad that they destroy the transistor in-

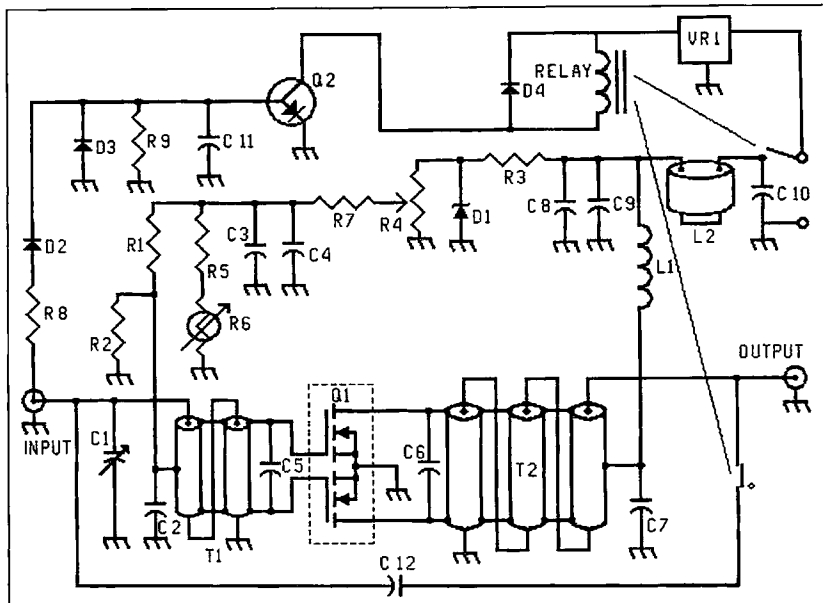

Figure 1. Schematic for the MRF175GV amplifier.

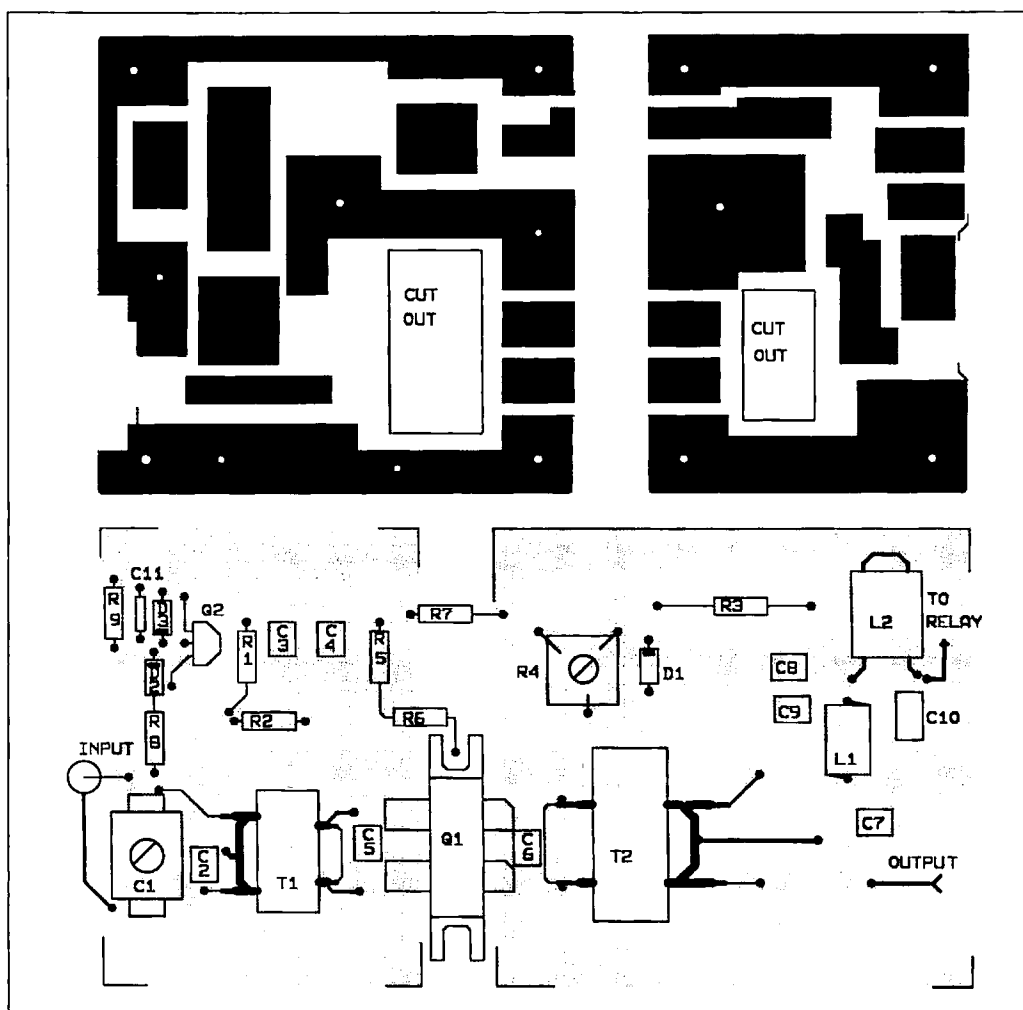

Figure 2. Circuit board.

Figure 3. Preparation of the transformer coax. Cut the transformers to the lengths shown, and strip the outer conductors. The inner leads that are to be 5mm should have their outer conductors stripped 6mm and the leads that are to be 10 mm should be stripped 11mm. Then strip the insulator that goes between the inner and outer conductors, leaving 1mm of insulator as shown, which will leave the inner conductors bare at the proper lengths.

stantly—especially when operated with more than 20 volts on the drain. If you intend to use the amplifier exclusively above 100 MHz, the beads can be left off the output transformer to get greater efficiency. In addition to stabilizing the amplifier, these beads can also aid in heat dissipation—something that is critical if the amplifier is to be operated at its maximum power. As for putting beads at the input transformer for use above 100 MHz, they should be installed if the am-

plifier will be operated at more than 20 volts. For operation below 20 volts, generally more power is obtained from the amplifier if they are left off—especially at frequencies above 200 MHz. However, the amplifier is more broadband if the input beads are left on.

Instructions for installing the beads are included if you order them from CCI. I used only a weak kind of glue, such as a little dab of silicone rubber, to hold the E ferrite beads to the I beads because I anticipated taking

them off. The input E bead ordered from CCI fits the 9:1 transformer they sell but is a bit large for a 4:1 transformer. Therefore, I filed down the E bead until it made a tight fit. The I beads need to be glued to the heat spreader after the circuit boards are installed, but before the transformers are soldered to the circuit boards.

A rectangular hole needs to be made in the output side of the box for the relay. If you do not have the tools to cut a square hole you can drill several small holes inside the area of the opening. Then use a hacksaw to further cut the area into straight sides. I deliberately made the cutout smaller than the dimensions shown because I did not want the relay socket to fit too loosely. In order to have a tight fit, I used a file to gradually increase the opening to the dimensions necessary for the relay socket. See Figure 5 for the positioning of the relay and the input and output connections.

When the box and circuit board have been properly prepared you are ready to assemble the amplifier. The heat sink, box, and heat spreader fit flush together; they should be sanded to eliminate burrs. Thermal heat sink compound should be applied between these parts as they are placed together. I used Radio Shack 276-1372 compound for this project. However, no thermal compound should be put on the circuit boards, which are raised above the heat spreader by means of washers (see Figure 6). The leads of the power transistor will need to be bent sharply upward—especially the output (drain) leads. Separating the boards from the heat spreader reduces heat on the components on the boards. It also makes the transformers fit flat on the boards when ferrite coils are used, instead of being elevated above the boards as they would be if the circuit boards were not elevated from the heat spreader.

The heat sink, box, heat spreader, and circuit boards are bolted together, using five bolts for each board. See Figures 2 and 6. I recommend that you don't tighten the bolts holding the boards in place until the transistor is bolted securely.

The power transistor should be placed on the board next. Use care in handling a field-effect transistor as these devices are subject to being destroyed by static buildup. When handling FETs, pick them up only by their sources. It is a good idea to wear a grounded wrist strap and to work on a static-free table using a grounded soldering iron. Once the device is soldered in place the danger from static buildup is minimized.

The transistor is mounted between the two circuit boards on the copper heat spreader. Thermal heat sink compound must be used when mounting the transistor. Be careful not to mount the transistor backwards—that's easy to do. The two flanges that have one of their corners cut are the drains; the other two are the gates. The leads on the output side of the transistor are bent sharply upward, but be careful not to break them. Also, there is a chance of the output leads shorting to the unused side of the board. One way to prevent

Figure 4. Preparation of the transformers. The leads between the transformer windings should be as short as possible. Bend the coax and bend the leads till they touch tip to tip, and solder the tips together. When properly assembled, an ohmmeter check will show a closed circuit between the two ends of the transformer leads and an open circuit between the inner and outer conductors. The mistake made on the bottom right drawing is easily made by persons assembling the transformers themselves. Nothing feels worse than getting the transformer assembled and having to redo it.

this is to etch away a small part of the output board near the transistor. See Figures 2 and 6.

Once the transistor and circuit boards are mounted and their bolts tightened, solder the flanges to the transistors. The transformers can be positioned now and soldered, completing the installation of the circuit boards. Then the last of the components can be soldered in place—VR1 and C12—as well as the connective wires for the receive circuit and the wire that provides the power for Q2. See Figure 5.

Before applying voltage, it is a good idea to do a few continuity checks. See if there is zero resistance from the voltage input to the drain of the transistor. Then check for shorts between the drain and ground and between the gate and ground. If you find shorts, do not proceed until the trouble is corrected. Both the input and output, however, should have a short to ground.

Checking It Out

When the resistance checks are made, you are ready to test the amplifier. Connect the input to a handie-talkie or other low-power transmitter and the output to a dummy load that has some kind of power indicator. If you have a spectrum analyzer, so much the better. A dummy load wattmeter will do—so will a dummy load with an SWR and relative power indicator placed between the amplifier and the dummy load. Be sure the dummy load is capable of handling more than 200 watts.

When applying voltage, put no more than 12 volts to the amplifier at first. Once voltage is applied, quickly check the voltage on the gates. This voltage will vary, depending on the adjustment of R3. For now, adjust R3 until the gate voltage reads approximately 2 volts. The gate voltage should not exceed 6 volts.

If you wish, you can check out the amplifier portion of the project before you check out the receive portion. To do this, do not connect one side of R10. However, once the amplifier is tested and R10 is reinstalled, it will have to be realigned.

Once the voltage on the gate is 2 volts, ap-

Parts List		
C1	Arco 404 mica trimmer, 8-60 pF or equivalent	Available from CCI.
C2, C3, C7, C8	1000 pF chip	CCI no. C1210C NPO 200V
C4, C9	0.1 mF chip	CCI no. C1813 BX 100V
C5	200 pF chip	ATC 100B 300V
C6	In parallel: 100 pF chip 130 pF chip	CCI no. C1210C NPO 50V ATC 100B 500V
C10	.47 mF chip	CCI no. C2225 BX 100V
C11, C12	.001 mF PC mount capacitor	Radio Shack 272-126 (or equivalent)
D1	8.2 volt zener	1N5923A or 1N756A, available from CCI.
D2, D3, D4	1N4148 high-speed switching diodes or equivalent	Radio Shack 276-1112 (for 10 diodes) or 276-1620 (for 50 diodes)
L1	10 turns AWG # 16 enamel wire, close wound, 1/4" i.d.	
L2	CCI VK 20/4B RF choke or ferrite beads of suitable material for 1.5—2 mH total inductance.	
Q1	Motorola MRF175GV	
Q2	2N4401 NPN transistor or equivalent	
R1	1k 1/2 watt	
R2	10k 1/2 watt	
R3	330 ohm 2 watt	
R4	1k variable trim resistor	CCI 3386P-102 or equivalent
R5	6.8K 1/4 watt	
R6	10k (25C)-2.5K (75C) thermistor	
R7	2k 1/2 watt	
R8	100 ohm 2 watt	
R9	10k 1/4 watt	
Relay	12 volt DPDT, 15 amp contacts	Radio Shack 275-218 and 275-220 relay socket.
T1	4:1 impedance ratio RF transformer. Can be made of 25 ohm semirigid coax, 47-52 millimeters outside diameter.	
T2	1:9 impedance ratio RF transformer. Can be made of 15-18 ohm semirigid coax, 62-90 millimeters outside diameter.	
NOTE: Both T1 and T2 are available from CCI. If you don't buy the transformers fully assembled you will need magnetic cores for the transformers. For T1 use Fair-Rite Products Corp. #9461012002/9361021002 E (or type 75-26 E and 1 Micrometals powdered iron core). For T2 use type 100-8 E and 1 Micrometals powdered iron core). See text.		
VR1	12 volt regulator	Radio Shack 276-1771
Connectors	Type N chassis mount female	Radio Shack 278-152 (or equivalent)
Optional	Radio Shack auto cigarette lighter power cord	#276-021
Circuit boards for this project are available for \$7 plus \$1.50 S & H from FAR Circuits, 18N640 Field Court, Dundee IL 60118.		

ply a 0.5 or 1 watt RF signal to the input of the amplifier. The relay should click on. If it does not, adjust C1 until it does. If the relay still does not come on, there is either a component breakdown or an error in construction. Once the relay has engaged, see if there is any output indication. Adjust capacitor C1 and R3 for maximum output. One good feature of this amplifier is that there are only two adjustments to be made: C1 and R3.

All this sounds simple, and it usually is. However, these amplifiers have a tendency to go into oscillation. Turn off the exciter, and

see if you still get a power indication on the wattmeter. If so, the amplifier is oscillating. Back off from R3 until the oscillation stops. C1 may also be adjusted. The trick is to get the maximum power out of the amplifier without it going into oscillation and remaining in that state after the drive has stopped.

When properly adjusted, the amplifier should give out more than 30 watts at 12 volts with 1 watt drive. At this point, you can increase the power of the amplifier by gradually applying more voltage to the drains. Never exceed 28 volts on the drains, and never let the voltage on the gates exceed 6 volts—if even that much.

If you are content to use only 14 volts (the power available in most automobile electrical systems), the amplifier can be used for continuous duty operation on all modes. At this voltage the transistor can withstand infinite SWR and any other conceivable abuse (except overdriving) and should easily outlast its owner. Notice that the amplifier gets warm after only a few minutes—even at this power level.

A word of caution: Some late-model automobiles are equipped with computers that will break down if a transmitter putting out more than 10 watts is used. This can stop the engine and lead to a thousand-dollar repair bill. Check your automobile owner's manual.

Once the transmitter is functioning, you are ready to test the receive circuits. Since the receive circuit consists of nothing more than a relay and capacitor C12, there should

Figure 5. The front and back sides of the box, showing the relay mounting and relay connections. The hole near the relay which allows DC into the box should be approximately 1/4" diameter. The rectangular opening for the relay should be 1" by 7/8". The holes for the "n" connectors should be 9/16".

VIDEO SWITCHER

W & S System (Div. of Westinghouse) # VCM-2001 The VCM-2001 video control module allows you to record from a cable converter or other program source while watching regular TV, or you can record from TV while watching cable or other source. Easy to hook-up and operate, the front panel has 3 soft-touch pushbuttons and LED indicators. Eliminates the need for cumbersome and inefficient mechanical AB switches and splitters. 9" X 5" X 2.4".
CAT # VCM-2001 \$19.95 each

ULTRASONIC TRANSDUCERS MATCHED SET

Panasonic transmitter/receiver pair. Ideal for remote control systems, burglar alarms, flow rate detectors etc. Transmitter: # EFR-OHB40K24 0.5" dia. X 0.37" Receiver: # EFR-RUB40K25 0.63" dia. X 0.48" Center frequency: 40 KHz. Band width: 4KHz +
CAT# UST-23 \$2.00 per set

TWO CHANNEL COLOR ORGAN

Create your own light shows. Electret mike on control board responds to music or other sounds causing lights to brighten and dim depending on frequency and volume. 120 Vac input and output. Provisions for two light strings, up to 200 watts per channel. Separate sensitivity controls for each channel. 0.25" qc terminals for output. Lights not included. 4.25" X 3.85". Hook-up diagram included.
CAT# CORG-1 \$6.50 each

4 DIGIT ALPHANUMERIC INTELLIGENT DISPLAY

Siemens # DL-2416T End-stackable, four digit display module with built-in CMOS memory/decoder/driver. High contrast, 160" high magnified red characters. Direct access to each digit independently and asynchronously. ASCII format. 5 volt logic, TTL compatible. Module size: 1" X 0.8" X 0.25". Includes specs and instructions. Sells elsewhere for as much as \$19.95.
CAT# DL-2416T \$4.95 each

12 VDC 500 MA WALL TRANSFORMER

Panasonic # KX-A11 WHITE - U.L. listed. 12 Vdc wall transformer. 2.1 mm co-ax plug with center negative.
CAT# DCTX-125W \$4.50 each • 10 for \$30.00 • 100 for \$265.00

Figure 6. Bolting the amplifier parts together. Note that the flanges of the output of the power transistor have to be bent upward. The output of the transistor can short to the bottom of the circuit board unless a small part of the bottom of the board is etched. See Figure 2.

Be careful to make the input and output connectors touch on the circuit board, or the amplifier may not work at 225 MHz. Solder the inputs and outputs directly to the foil of the board without using lead lengths. A BNC connector could be used in place of the type N connector used in this experiment.

be no problem if everything was installed correctly.

How It Works

When an RF signal is put into the amplifier, a small portion of it flows through R12 and D2 (see Figure 1), which turns on Q2. This action causes the relay to engage, thereby disconnecting the receive circuit and allowing voltage from the power supply to enter the amplifier.

Resistors R1 through R7 supply the proper

bias voltage to the gates of Q1. The power supply voltage goes to the drains through the T2 center tap.

The transformers are wound in such a way that they match the 50 ohm impedances of the input and output over a range of several octaves. The transformers' ratios are the ratios of the square of their turns. For instance, one turn would give a 1:1 ratio, two turns a 1:4 ratio, three turns a 1:9 ratio, and four turns a 1:16 ratio.

HAM HELP

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS 73 MAG Message Area #4. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 924-9343). Use upper- and lower-case letters where appropriate. Also, print numbers carefully - a 1, for example, can be misread as the letters l or i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

transceiver. Photofacts preferred. I will pay for copy and postage. Brent Putnam N8UBD, 12110 Mayfield Rd. #6, Cleveland OH 44106. E-mail on college internet bwp2@po.cwru.edu.

Needed: Schematics, Parts/Track Maps and Component Location Diagrams for Genave Alpha/500 Nav/Com. I want to use the receiver for 121.5 MHz ELT locator. I will pay reasonable costs. Thank you. Lewis Moore N4DRJ, P.O. Box 52, Cornelia GA 30531. (706) 778-4716.

Wanted: Information on satellite operation: How to get started, uplink/downlink frequencies, telemetry info, equipment needed, antennas, etc. Can anyone suggest a good up-to-date reference source that can give me complete information? Also, I am interested in contacting hams who are vegetarians (for recipes and ideas). Contact me on the local Spokane WA 147.20 rpt, or write to: Doug Cole N7BFS, P.O. Box 72, Spokane WA 99210.

Needed: Manual/schematic, or copy, for Zenith Color Monitor, Model ZVM131, Service No. CD13MVR005. Ed Reichert N2BGE, 462 Timberline Dr., Mt. Laurel NJ 08054.

I am in need of the schematic and/or SAMS Photofacts for the HyGain II CB

An Experimenter's Power Supply

An adaptable multi-voltage supply.

by Fred Reimers KF9GX and Mark Reimers

After you have built a special project and want to power it up, you connect the completed project to your power supply. But what do you do when the project requires special voltages, different from the normal 12 VDC power supply, like +9 and +5 and -5 and -9 VDC? You say to yourself, "I need a multi-voltage power supply that also has negative voltages, and I have to be able to set the voltages to accommodate different projects."

Switching Supplies vs. Standard Transformer Power Supplies

There have been a number of articles on power supplies over the past years. Most of these have been single- or dual-voltage.

Switching power supplies have a lot to offer. They provide higher efficiency at higher currents than transformer supplies. Switching supplies are smaller and weigh much less than transformer supplies. An 8-amp transformer supply could weigh six to 10 pounds, while a switching supply could be as light as two pounds. Switching supplies are easier to filter and offer better regulation.

Why haven't there been published construction articles on switching power supplies? Because switching power supplies are much harder to design and it's difficult to keep the radiation down. Without a large amount of RFI filtering and shielding, you could never operate a radio near a switching power supply.

Switching power supplies are not as reliable as conventional transformer power supplies, though the commercial supplies are becoming as reliable as their transformer counterparts. The weakest links in switching supplies are the switching devices (transistors or FETs), due to the dI/dt transients un-

der load conditions. The biggest reason why standard transformer power supplies are still popular with us builders and experimenters is the availability of parts and the ease of building a supply. With the availability of transformers, regulator ICs (ie. the 723, 78xx series and 317/337 devices), and capacitors, it is easy to build a transformer power supply.

We wanted to make a supply that was simple, yet versatile enough to fit all low power multi-voltage applications. The supply we came up with has six outputs that can be independently adjusted. We set the outputs to +12, +9, +5, -5, -9, and -12 VDC.

"The biggest reason why standard transformer power supplies are still popular with us builders and experimenters is the availability of parts and the ease of building a supply."

Circuit Description

The power supply is made up of two independent circuits, the positive and the negative voltage sections. Diodes D1-4 and D5-8 rectify the AC voltage and C1 and C2 filter the DC voltage for the positive and negative sections. Capacitors C3, 5, 7, 9, 11, and 14 are placed at the input of each of the regulator ICs for regulator stability; C4, 6, 8, 10,

12, and 13 are placed at the output of each regulator for improved transient response, i.e. to improve the output voltage overshoot and undershoot response when a load is applied or removed from the output. The negative and positive sections are divided into three separate regulator circuits. The LM317T and LM337T regulator ICs, chosen because of their availability, require only two external parts, can be configured as variable regulators, and are rated at 1.5 amps (with proper heat-sinking). The voltage adjust resistor was chosen as 5k, but lower values could be used to increase the adjustment sensitivity and to lower the maximum adjusted output voltage.

The data book (Note 1) gives the equation for the output voltage as:

$$V_{out} = V_{ref} (1 + R2/R1) + I_{adj} R2$$

V_{ref} is a constant 1.25 volt that is maintained between the output and adjust terminals by the regulator. Thus, the lowest voltage that can be achieved from the LM300 series regulators is 1.25 volts. Using the above equation, the adjustable resistor value is 2,244 ohms for a 13.8 volt output. Using a 1k pot would yield an output voltage range of 1.25 to 6.8 volts. Depending on where the output voltage of the individual regulator is set, the LED current-limiting resistor should be adjusted to keep the LED current in a safe operating range, as specified by the LED manufacturer. We like to keep the LED current between 10 and 20 milliamps.

To calculate the LED current for the output voltage setting you want, use the formula:

$$R_{LED} = (V_{out} - 0.7) / 0.015$$

The 0.7 is the LED voltage drop and 0.015 is the LED current of 15 milliamperes. For example, for V_{out} of 12 volts, the current-

Photo A. The experimenter's power supply.

Photo B. The completed circuit board.

Photo C. Bird's-eye view of the circuit board and transformer placement.

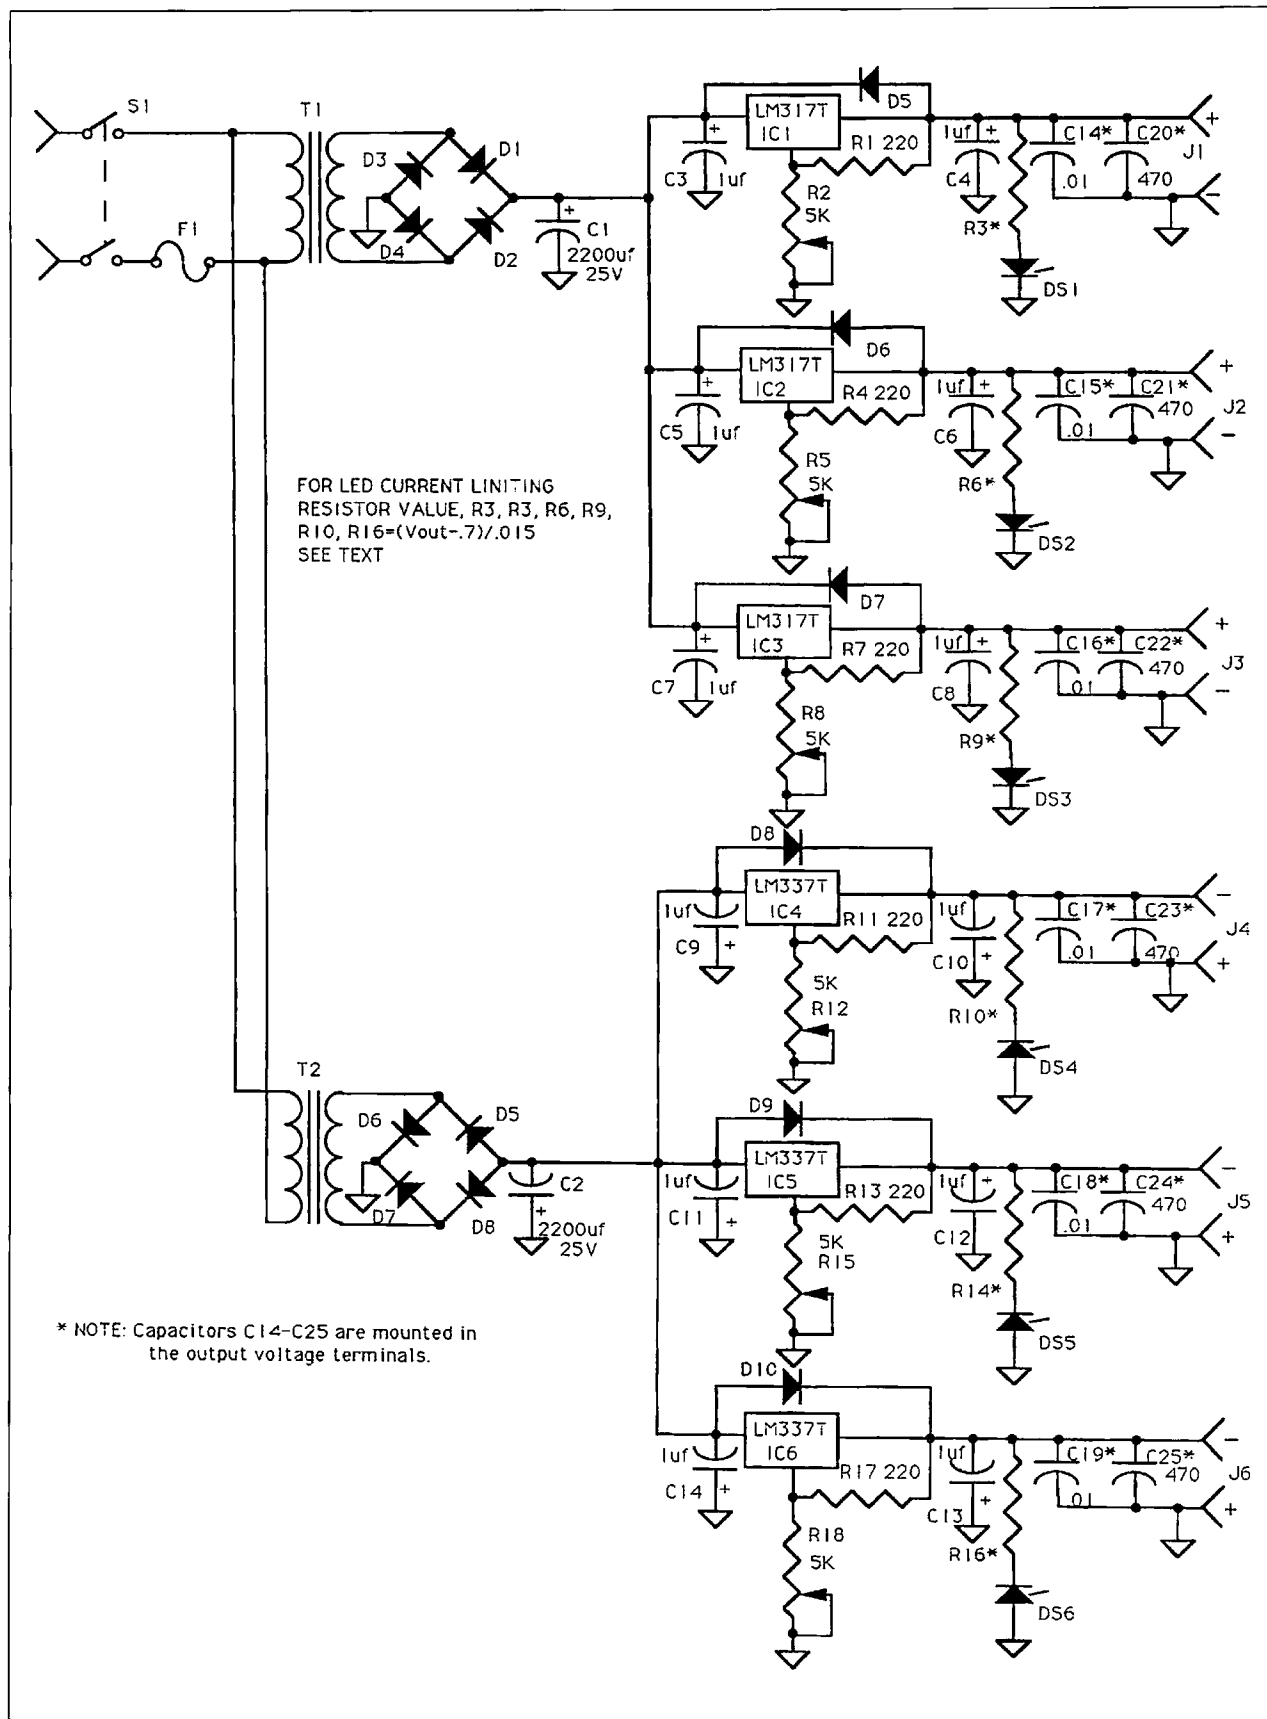

Figure 1. Schematic for the switching power supply.

limiting resistor should be 750 ohms. A 680 or 820 would also work, keeping the current in the 13.78 to 16.6 milliamperes range. For a lower value of V_{out} of 5V, a 270 or 330 ohm resistor will do the job. We used a 680 ohm LED current-limiting resistor. This kept the LEDs in a safe operating limit at the higher voltages and still allowed the LED to light dimly when the output voltage was adjusted to 5 volts.

We chose a 3 amp transformer because of its availability and current rating. The available 3 amp source current is divided between the three regulator circuits. Two separate transformers were used for the AC to keep the positive and negative voltages isolated. We mounted the transformers off the PC board.

A Word About RFI

All active regulated power supplies work great until you use them to power up the transmitter project you just finished. Have you ever wondered why the voltage drops or increases drastically when you key the transmitter? This is due to RF getting back into the regulator of the power supply. To prevent this, put 0.01 and 560 pF or 470 pF capacitors across the voltage output terminals.

A word of caution: The LM317s and LM337s like to have a load on them at all times. If the LEDs are not installed, and with no load on the regulator, the output voltage could float up to the input unregulated voltage. The LED current is sufficient to keep the output voltage from floating up.

Construction

The project is assembled in a Radio Shack box #270-250. A bigger box may be required if heat sinks and/or front panel adjustments are used. The AC power switch should be a DPDT type which disconnects both sides of the line when the power supply is turned off. The fuse should be in the high side of the power line and use a three-prong AC plug on the end of the power cord. The regulator ICs are rated at 1.5 amperes but will require heat sinks for the lower voltage applications that draw more current. For example, if the output is adjusted to 5V and the load current is 0.75 milliamps, there will be almost 10 watts of power dissipated into heat in that regulator IC. We did not show the heat sink in the power supply pictured in this article. When adding the heat sink, remember that the tabs on the LM337Ts are connected to the input voltage and the tab on the LM317T is connected to the output voltage. Mica insulating hardware (such as Digi-Key 4671K-ND or 4672K-ND, or Newark 46F7847 with insulating shoulder washers) must be used to isolate the tabs of the regulators from each other. The power supply is assembled on a nice 4" x 2.75" PC board with a screened legend for easy assembly. The board is available from FAR Circuits (Note 3). The transformer is external to the board and connects to the T1 and T2 points on the board.

The ICOM IC-W2A Dual-Band Handheld

Two radios in one!

ICOM America, Inc.
2380 116th Ave. N.E.
Bellevue WA 98004
Telephone: (800) 999-9877
Price Class: \$500

It never failed. No matter which rig I happened to have at any given moment, all the action seemed to be on another band! If I had my 2 meter HT, I would miss my normal commuting skeds on 440 MHz. Yet whenever I had my 440 MHz HT with me, I would always find some need to get on the more heavily populated 2 meter band. The thought of carrying around the extra weight of two full-size handie-talkies and a couple of heavy-duty battery packs was not an appealing one.

There was only one solution: It was time to upgrade to one of those new, compact, dual-band handhelds! Having had excellent results (with both performance and service) with my older ICOM HTs, I selected the ICOM IC-W2A.

The ICOM IC-W2A is a full-featured dual-band handheld measuring only 6.7" high, 2.1" wide, and 1.4" thick. The rig weighs in at only 1.2 lbs. As delivered, frequency coverage is 140-150 MHz and 440-450 MHz transmit, 136-174 MHz and 440-450 MHz receive. Despite its small size, the W2A offers a full 5 watts output (at 13 volts) on both bands, four scanning modes, 60 memories (30 per band), simultaneous receive on both bands, full crossband duplex operation, and a host of other functions. Unlike many other HTs, the W2A comes equipped with a heavy-duty 7.2 volt, 1,000 mAh battery pack and a multifunction PL encoder/decoder as standard features. Other noteworthy features include a 24-hour clock, power on/off timer, two power-saver modes, four 15-digit autodialer memories, and a pager mode.

Although I had seen photos and dimensions of the HT prior to ordering the rig, they still did not prepare me for the surprise I experienced when I opened the box. How could ICOM fit all those features into such a small package? Although the W2A may sound large due to its 6.7" height, the heavy-duty BP-84 battery pack takes up three of those inches; the actual radio itself is only 3.7" long! The antenna connector, speaker and mike jacks, external power jack, rotary tuning knob, and dual concentric volume/squelch knobs are placed on top of the transceiver. An LCD display shares the front panel with the internal speaker/mike, an RX/TX status indicator LED, and no less than 22 individual buttons—no small feat considering the W2A's 6.5-square-inch front panel. The function and

PTT switches are located on the left side of the case. The lower two-thirds of both sides of the case are contoured for an easy and comfortable grip.

The first thing I noticed about the W2A is how naturally it fits in the palm of the hand. After using this HT for a few hours, going back to my trusty O2AT/O4AT suddenly felt as if I were holding a brick! Although the W2A is compact, it does not feel cheap. The rig has a slightly heavy (for its size) feel, and the metal back provides structural rigidity while serving as a heat sink for the output modules. Squeezing the rig, even hard, caused none of the squeaking, popping, or snapping sounds common to many plastic-cased radios. The W2A felt like a quality, high-grade piece of electronic gear.

Features

The ICOM W2A is chock-full of useful features. There are 30 memories, plus a VFO memory, call channel memory, and two band-scan memories for each band. Each of these is capable of storing not only frequency and offset, but custom offset, PL encode mode and frequency, PL squelch mode, and channel scanning lockout information as well. Unused memories can be masked. Memory backup is handled by an internal rechargeable battery, although ICOM provides no information as to how long memory contents can be retained with no external power.

There are five different scan modes available. The simplest is VFO scan mode. Enter a frequency into the VFO memory, and hit the scan up or scan down key. This has the same effect as tuning a receiver across its tuning range. Programmed scan mode allows the user to enter two frequencies into scan memory, and the radio then scans continuously between these two limits. This is similar to what scanner manufacturers call search scan. Memory scan mode scans all 30 memories, regardless of their lockout or "skip" settings. Memory skip mode scans only those memories which have not been assigned lock-out status. Finally, frequency skip mode allows the user to enter up to 20 frequencies in memory, and perform a VFO or programmed band scan. The rig will then ignore these frequencies while scanning. If this weren't enough, all these modes have two resume modes: timer and pause. Timer resume

stops the receiver when a signal is received, pauses for five seconds, and resumes scanning. Pause resume mode stops the receiver when a signal is received, and will not resume scanning until two seconds after the signal ceases.

The ICOM W2A also comes equipped with a multifunction PL board which allows full PL encode/decode functions. The PL unit can be used not only as an encoder to access closed

repeaters, but also as a subaudible tone squelch which will keep the receiver squelched regardless of channel activity until the unit receives the proper PL tone. When the right tone is received, the W2A can be set to either open the squelch and receive the signal, or to emit a series of pager-like beeps for 20 seconds. Pushing the PTT button cancels the PL alarm mode and returns the rig to PL tone squelch mode, allowing reception of the desired signal.

When setting PL tones, the actual tone frequencies are displayed on the LCD, instead of the archaic two-digit alpha-numeric codes used on some older rigs. Since the PL board is actually two units in one, it's possible to transmit with a PL tone on one band and activate the PL squelch on the other band using a different PL tone. It is also possible to operate both receivers in PL squelch mode using different tones on each band. Although the PL tone squelch functions during crossband repeat mode, the PL encoder does not.

The W2A also sports a pager/code squelch mode which is activated by a sequence of DTMF touch-tones. This mode allows for all call, group call, and individual call modes, which allow a single transmission to trigger all receivers, a subgroup of receivers, or a single receiver, respectively. The pager tone sequences, as well as the pager decoder codes, are entered into five memory positions reserved for this function.

Other nice touches include tuning increments which can be set at 5, 10, 12.5, 15, 20, 25, 30, and 50 kHz steps for both VFO and scan modes. In addition to these, 100 kHz and 1 MHz steps are available when using the tuning knob at the top of the radio. Frequencies can also be input directly from the keypad. Transmit offset frequency is programmable in 5 kHz steps from 5 kHz to 10 MHz. The IC-W2A also features a keyboard lock function which locks out all keys except the dial light and high/low power switch, and a PTT lock which makes it impossible to key the transmitters.

A number of features specifically address power consumption and battery life. Transmitter power output is selected from four steps rather than the more common hi/low setting. "Auto off" mode shuts off the radio if no transmissions or key strokes are made within a specified time period. Prior to shutting down, the rig emits a number of beeps to warn the user of its intentions. "Power saver" mode puts the W2A into standby mode after five seconds of inactivity. The unit will then turn on every few seconds and check for a received signal. If the channel is quiet, the W2A goes back to sleep and the cycle repeats. If the channel is busy, the radio will remain on until activity ceases, then resume power saver mode. The "on/off" duty cycle is selectable between a 1:4 and a 1:16 ratio. "Power saver" works only when monitoring a channel—it does not function when using any of the scan modes.

Ironically, some of the W2A's biggest features are those which ICOM does not mention in the owners manual: extended wide-

Figure 1. VHF receiver sensitivity (55-420 MHz).

band receive and crossband repeat. Both of these features are accessed through simple keyboard sequences without the need to open the radio or perform any hardware modifications.

Modifications and Operation

To open the coverage range of the receiver, turn the radio off. Then turn the radio on while simultaneously pushing the [LIGHT], [B], and [#] keys. After I performed this proce-

cedure, the receiver tuned from 55-410 MHz (including AM aircraft) on the VHF band. The UHF receiver covered 350-525 MHz and 725-1026 MHz (FM only)! *Warning: Please remember that it is illegal to monitor cellular phone conversations!* As expected, receiver sensitivity varied widely across these ranges. Due to high-pass filtering on the VHF band for image rejection purposes, don't expect to hear much below 118 MHz. Figures 1-3 show receiver sensitivity in dBm for a 20 dB quiet-

Figure 2. UHF receiver sensitivity (350-525 MHz).

ICOM IC-W2A UHF RECEIVER SENSITIVITY

Figure 3. UHF receiver sensitivity (725-1025 MHz).

ing figure. For those not familiar with dBm, the sidebar table cross-references selected dBm levels to microvolts. Although the LCD display goes from 0-1300 MHz, these figures represent actual receive band limits as confirmed with a signal generator.

After completing this modification, access the radio's setup menu as per the instruction manual. Step through the options with the [UP] or [DN] keys and you will find a new parameter not listed in the ICOM manual, called PL. This sets the highest MHz place which can be programmed by the direct keyboard entry mode, selectable between 1 MHz, 10 MHz, and 100 MHz. Turn the tuning knob to set the PL parameter to 100, then press either the PTT or [CLR] to exit the setup menu. The VFO can now be tuned to any frequency within its extended receive range by simply entering the numbers from the keypad. For example, say the VFO is set at 440 MHz and you want to tune to 903.525. Simply enter: [#] [9] [0] [3] [5] [2] [5].

To enable the crossband repeater function, the above wideband receiver modification must be performed first. To activate the repeater, enter the desired frequencies and modes (simplex or duplex) and push the [VMAIN] key. While holding down the [FUNCTION] key, press the [2] key and then the [ENTER] key. The keylock [L] symbol will now flash on the LCD display, indicating that the unit is in repeat mode. To cancel repeat mode, push the [FUNCTION] and [ENTER] keys simultaneously.

Lab tests were performed using a Hewlett-Packard 8654A signal generator and 403B AC voltmeter, a DigiMax D-1200 frequency counter, a Measurements 920 peak deviation meter, a Daiwa wattmeter, a Heathkit Cante-

na dummy load and SM-5258 THD analyzer, a B&K 1630 DC power supply, and a Fluke 95 scope-meter. For frequencies above the H-P 8054's 535 MHz limit, the signal generator's second harmonic was used. This harmonic was measured and found to be 30 dB down from the fundamental. Then 30 dB was subtracted from the signal level settings. All graphs and/or charts show the corrected figures.

The ICOM IC-W2A utilizes dual-conversion receivers with a 30.85 MHz 1st IF (35.80 MHz on UHF) and 455 kHz 2nd IF. Receiver sensitivity measured 0.12 μ V for a 12 dB SINAD on both 2 meters and 70 centimeters. The 20 dB quieting level measured 0.22 μ V. Receiver sensitivity was essentially flat across both ham bands, and varied widely across the extended receive range, as shown in Figures 1-3. Image rejection measured 72 dB on 2 meters and 77 dB on 70 centimeters. Audio output measured 150 mW with 3% THD. Maximum audio output using ICOM's

dBm Versus Microvolts

dBm	μ V	Volts
0	220,000	0.22
10	70,000	0.07
20	22,000	0.022
30	7,000	0.007
40	2,200	0.0022
50	700	0.0007
60	220	0.00022
70	70	0.00007
80	22	0.000022
90	7	0.000007
100	2.2	0.0000022
110	0.7	0.0000007
120	0.22	0.00000022

10% THD reference was 220 mW.

On the transmit side of things, peak deviation measured 5 kHz for voice and 2.5 kHz for DTMF tones. Transmit frequency was 20 Hz low on 2 meters and 40 Hz low on 70 centimeters. Maximum RF power output measured 6 watts at 13.8 volts and 1.5 watts when using the supplied BP-84 battery pack.

Power consumption measurements were taken at 7.2 volts to simulate realistic current drain on the battery pack during typical portable operation. Where different readings were obtained depending on band, the first value is for the VHF unit and the second value (in parenthesis) is for the UHF unit. Unless otherwise noted, measurements were taken with only one band in operation. The receiver drew 50 (70) mA during no-signal squelched state, 150 (170) mA for full audio output, and averaged 13 (18) mA in power saver mode. With both receivers on, power consumption measured 117 mA during standby, 220 mA for full audio output, and 21 mA in power saver mode. Activating the backlight added 15 mA to the battery load. Transmit current measured 410 (625) mA at the lowest power setting and 780 (970) mA at the highest power level. At 13.8 volts, transmit current measured 1.5 (1.7) amps at maximum RF output.

Real-world use tests were conducted over a six-week period during which the W2A was used in base, portable, and mobile environments. Audio output was ample for base and portable operations, but a little light for mobile use in a noisy vehicle. The LCD display was easy to read from a wide range of angles. The dual LED backlight provided sufficient light to read the display at night. Very few intermod products and virtually no birdies were noted on either band, even when operating in areas of high RF clutter around Springfield, Massachusetts. Those that did occur were usually well outside both ham bands in the W2A's extended receive range. The operator's manual was relatively clear and easy to understand, with only a few confusing sections.

Although it was easy to inadvertently hit a key on the crowded keyboard and QSY to another frequency or send the rig into scan mode, the keylock feature proved extremely useful for preventing such accidents during mobile operation by locking out all keys except PTT, power, light, and hi/low RF power. The PTT lockout feature proved handy when leaving the rig in the presence of co-workers and other non-hams, and could be a real plus for hams with children. The W2A's small size and light weight also made for comfortable, extended-duration QSOs while commuting to work. Although the metal rear cover became fairly warm during long-winded QSOs, it never became uncomfortable to the touch. The W2A's mechanical construction also appeared quite durable; it survived a few accidental drops of two to four feet (definitely not recommended!).

The W2A's lack of sufficient low-battery warning was annoying. The radio would operate flawlessly right until the battery went

Async Comms, Part 2 (Finally)

Whoops! The flurry of paper, bits, and phone calls here at N1EWO Central Control sucked up this second half (continued from the March 1993 "Packet & Computers" column) of our async primer and spit out the first half of a different series. For those of you who got confused, it wasn't your fault—it was mine. So, the result is that we will have interleaved multipart columns for this and next month.

When we last left our data, it was timing itself—allowing us to communicate asynchronously. Let's review a little. The term asynchronous (async) means "without the same time." It comes from the Latin roots "a," for without; "syn," for the same; and "chronos" for time. As you can see, it's a strange sort of word. It sets up a complicated idea and then adds "not." What this whole mess means to digital communications is that the data on an async link does not depend on a common "clock"—regulating signal—to figure out each bit as it goes by.

Before I completely confuse you, let's take a step back. Why is time important at all? OK, binary communications (that use only two states—on and off, high or low, etc.) depend upon time to create combinations that can be interpreted as characters. The "canvas" upon which the character is "painted" is time. In contrast, printed communications use space as their medium. As you look at written communications, you are concerned with how the marks or the paper (or display) relate to the space they occupy. The terminal's space is time. It concerns itself with the relationships that the bits form in time to figure out their content. This makes time the medium upon which the data is written. Don't worry if you don't get this, it is not critical to understanding this stuff. If you do get it, though, it will help you understand.

So, we are dealing with something that happens over time. The receiving station has to know when a bit (the smallest unit of data—a binary 1 or 0) has gone by. You'll get a better feel for this if you think of a data stream that has, say, seven 1's in a row. Without some sort of timing, the receiving station would have no way of telling that this was not just one big 1, since the signal will not change for the duration of the seven 1 bits. The obvious solution is to have one side be in charge of the timing. This is called synchronous communications. In this scheme we send a standard clock signal along with the data, and the data stream is

interpreted by this timing. In our seven 1's example, seven ticks of the clock would count off the seven bits as they went by. This works fine, but while it is conceptually simpler, it is more complicated to implement on a real data channel.

The alternative scheme is our subject—asynchronous communications. The name, async, is a bit confusing. While it implies that time is not important, this is not true. What it really means is that there is no master clock. The data is self-timing. Each async character has what are called "framing" bits. These are the start and stop bits that you are probably familiar with from setting in your communications software, or even from using dip switches inside a dumb terminal. These framing bits let the receiving station know that the character has started and stopped. This makes each async character its own clock. Well, at least to a point. You still need to know at what speed the data is being sent. It isn't a free-for-all. The framing bits let the receiver sync(hronize) to the bit sequence. There are standard data rates that must match.

Back to Earth

So, what's the practical upshot of this academic stuff? For those with a nuts-and-bolts bent, it means that for the TNC and computer to successfully communicate they must be set to the same data parameters. The most common setting, and the first to try if you don't know what is the right combination, is 7E1. 7E1 is shorthand for 7 data bits, Even Parity, 1 Stop bit. Let's break that down.

7 Data Bits

This means that the characters are made up of 7 bits. This is fine for the standard ASCII (American Standard Code for Information Interchange) character set. Seven bits allows for 128 different combinations—in this case characters. This is fine for most communications, but for graphics characters (which are in the extended ASCII set) or binary file transfer, which uses all 255 combinations that the 8 bits of a byte allow. (Note: Binary file transfer using 7 bits is possible, but it requires special software to encode and decode the information on each end.) Seven bits is the de facto standard because it is usually all that is needed, but 8 bits is a possible value as well.

Even Parity

The parity bit is used for error detection. You are unlikely to actually find software that does anything with it other than report an error. In other words, it is not used for error correction. In any case, it works like this:

The bits in the data are added together and the parity bit is set to a value that will make the result either even or odd, depending upon the setting. For example, in the case of an "e" the data bits, "1100101," add up to four. This means that for even parity the parity bit gets set to zero. This is because four is an even number. If the parity were set to odd, the parity bit in this case would be one—which added to four makes the odd five. Your main concern with parity is to set it the same on both ends.

1 Stop Bit

The stop bit is the complement of the start bit. Every async character has a start bit and at least one stop bit. You can set stop bits to 2, though. Again, your main concern is to match the two ends.

The Speed of Things

As I mentioned before, the rate of the data transmission must also match on both ends. Data rate is measured in bps (bits per second). It is also measured in bauds (named for J.M.E. Baudot, a French engineer from the 1800s). These two can be—but are not necessarily—the same. A baud is a state change or transition—say from on to off. A baud can transmit one or more bits. In the simplest case, bps = bauds because one bit is sent for each transition. This will be the case for the connection between your terminal and TNC. As soon as we start to discuss modems with data rates higher than 1200 bps, the picture changes.

Because modems work by changing data to audio and back again, the bandwidth (frequency range) with which they have to work puts a limit on how many bauds (transitions per second) they can transmit. Most modems are designed to work on voice channels which offer a bandwidth of about 3000 Hz. So to get around the relatively narrow bandwidth, high-speed modems use a technique that combines the frequency information of the signal (FSK—Frequency Shift Keying), and the phase information (PSK—phase shift keying). This scheme is called trellis encoding. It uses combinations of frequency and phase in a table that resembles a trellis, hence the name. This approach allows more than one bit of information to be encoded into each transition—or greater than one bit/ baud.

Practically speaking, you need to make sure that each end of the data link is set to the same speed. What should this be? My general purpose recommendation is 9600 baud. A good question is, "If the on-the-air data is only going 1200, why set the comm link at 9600?" Well, if the only data that was sent over the link was from the on-the-air link, that might make sense. But the TNC sends status messages, mail, and other traffic to the terminal. It is much more pleasant to work with the TNC at the higher data rate. On the other hand, it is not a requirement. While you might experience difficulties—like buffer overflow—

if you set the link below 1200 baud, it is not necessary to set it higher than 1200—it will work fine there.

The next part of this series will appear in two months. I will cover the software side of this confusing but vital part of packet radio.

The Survey Continues!

A few months ago I started publishing a set of survey questions which I thought I would run for a couple of months and then publish the results. Well, the response has been increasing rather than decreasing so I thought I would put them in here once again and give you another chance to respond. It's not too late, but this will be the last time I ask for responses. You can use E-mail or paper mail to answer the survey.

1. What is your callsign?
2. What is your license class?
3. What computer(s) do you use in the shack?
4. What operating system/environment version(s) do you use?
5. Which digital modes are you equipped for?
6. Which digital modes are you active in?
7. Which of these columns (month, year) has been your favorite (if any)?
8. What has been your biggest problem with computers in ham radio?
9. What would you like to see in this column?

10. Any comments:
You don't need to copy the questions, just put the number before your answer. Answer all the questions, or just the ones you want. Make the responses wordy or brief. I really want your feedback to make this column something you look forward to each month. Thanks so much for your participation.

Electronic Addresses
Packet: N1EWO@NICENI/OARY
(Note: I'd love to hear from you on packet—but not about the survey! This survey is the business of this magazine, and we can't do that on ham radio. A personal note or test message is just fine.)

Internet: jsloman@mcimail.com
(This is my preferred address.)
MCI Mail: jsloman
(This is the same as above, but direct.)

CompuServe: 71221,1143
(This is my least favorite place to get mail, but it is OK.)

Even if you don't answer any survey questions, I am very interested in anything you have to say. I can't answer every message—though E-mail has a much better chance. Many of you have written asking for help. You have not been forgotten; I am planning a "mail bag" column for the near future where I can answer the many similar questions that come in. For those of you who have written saying that you enjoy the column, thanks. For those of you who would like to see additions/changes, please write to me—it's the only way I have of knowing what you need and want. 'Til next month, 73 de N1EWO.

ICOM IC-W2A

Continued from page 39

dead, giving virtually no warning whatsoever. When the battery finally did run down, the only warning was a howling or oscillation in receive mode or a transmitter which cycled on and off if the PTT key was pressed. Once either of these events occurred, there wasn't enough juice left in the battery to even sign off. On two occasions I was unable to shut off the radio with the power button (which ties into the CPU and is not a hard-wired power switch). The only way to get the unit to stop howling or keying was to remove the battery pack. It would have been nice had ICOM used the front panel status LED to warn of an imminent dead battery condition a minute or so before the rig actually goes dead, as was done in the IC-2/3/4AT series of handhelds.

My biggest disappointment with the ICOM IC-W2A was its limited transmit frequency coverage on the 70 cm band. The W2A transmits between 440 and 450 MHz only. With its full crossband duplex modes, this HT would have made an excellent basis for a portable OSCAR AO-21 platform, had not the 435 MHz FM uplink frequency been locked out of the transmit range. A call to ICOM's tech line confirmed that there was a mod available to open the transmit range, but ICOM would not reveal the mod, stating that it was a "dealer mod." A call to two dealers proved fruitless, while a third dealer offered to perform the modification for a fee, but only if a MARS or CAP license was presented. ICOM would do well to provide a simple mod or upgrade the programming to enable transmit in the 430 to 440 MHz range. With an HT this advanced, they have truly limited its potential and missed a golden opportunity to introduce users to satellite communications.

Other drawbacks were minor, but equally irritating. These included an oddball DC power connector, the likes of which I have never seen anywhere other than on the pages of an ICOM accessory catalog. Although the battery packs are interchangeable between the W2A and the 24AT, forget the speaker mike or headset units. If you've ever charged an ICOM BP-4 in a BC-30 charger, you'll be as surprised as I was to discover that the W2A's

BP-90 battery cases cannot be recharged in a drop-in charger. Finally, the shape of the belt clip made it virtually impossible to hook the radio on a back pocket with one hand. Attempting to do so was an exercise in aggravation. The shape of the clip caused it to prefer plowing through material rather than sliding over it. The only way to engage the clip was to use one hand to pull on the pocket and place the material under tension, and use the other hand to force the clip down over the pocket lip.

A Bargain

All things taken into consideration, the best way to sum up the ICOM W2A is to call it a bargain. Although \$500 is not cheap for an HT, one must remember that the W2A is basically two completely independent single-band radios sharing a single case, and is capable of doing anything two separate HTs could do, except transmit on both bands simultaneously. The BP-84 heavy-duty battery and the included PL encode/decode board make the radio quite an attractive value. Toss in the wideband receive modification, and it's like getting a portable scanner for free!

The ICOM W2A is not for everybody. With so many features packed into such a small package, plan on spending at least four or five hours with the owner's manual learning what all those double and triple function buttons do. It took me about a week to learn my way around all the features and extras packed into this little HT. For those willing to take the time to read and understand the manual, the W2A is an exceptional rig.

Rating this HT on a scale of one to 10 was difficult. Receiver sensitivity, frequency coverage, features, ease of use, layout, appearance, and performance all deserved a solid 10. However, I could not overlook the unit's inability to transmit on legitimate 430 MHz satellite FM uplink frequencies, nor the difficulty experienced in trying to get it to do so. The incompatibility of some accessories between the W2 and 24AT, along with the weird power connector and lack of any advanced low-battery warning also pulled down the overall rating. On a scale of 1 to 10, I would rate the ICOM IC-W2A at 8-1/2.

An Everything Amplifier

Continued from page 28

Results

At 223 MHz the amplifier will put out more power than is legal for Novice operators. However, this power can be backed up to the legal 25 watts by adjusting R3. I tested this amplifier with my 1.25 meter handie-talkie, 2 meter handie-talkie, 6 meter transceiver, 10 meter mobile rig, a 10 MHz home-brew transmitter, and an HF rig at 3.5, 7, 10, 14, 17, 21, 24, and 28 MHz. The amp does not work well at 3.5 MHz, but it does at the other frequencies tested. At HF frequencies with only 13 volts from the power supply, 1 watt input gives a little more than 30 watts out. One point cannot be emphasized enough: Do not put more than 25 watts into this amplifier—so be careful if you test this amplifier with a transmitter that is capable of putting out more power than that.

If the amp is used for SSB, the relay may not want to stay engaged. It may be necessary to manually key the relay if you're going to use the amp on SSB or to design a circuit that will delay the relay from opening once it closes.

As the power supply voltage is changed, the bias will sometimes have to be adjusted. Furthermore, bias sometimes has to be changed if you go from one band to one of a much different frequency. The power gain of a broadband amplifier will go up at the lower frequencies, and if you switch to a lower frequency with no adjustment, the amp may go into oscillation.

Receive sensitivity is slightly reduced—especially at the higher frequencies. If you want to get the receive sensitivity back up to the level it would be without the amplifier, consider installing a broadband preamp.

Remember that FCC regulations, common courtesy, and good operating practice require the use of minimum power when operating on the airwaves. Also remember that experimentation is one of the main reasons for our hobby.

My thanks to the XYL, Carolyn KC4NBE, who encouraged me in the project and proofread the manuscript. Also thanks to Will Payne N4YWK, who worked with me on the project and gave me tips that enabled the amplifier to work.

Electronic Project Panel Labels

Let your computer help.

by Marion D. Kitchens K4GOK

After finishing the electronics on your latest project, the next matter at hand is a suitable enclosure, followed immediately by the problem of labeling. How do you make your electronic marvel look like a professional piece of work? There are a number of different ways to accomplish that task, all with various degrees of difficulty and varying qualities of results. Many hams resolve this problem with rub-on lettering, stick-on tape labels, etc.

With the advent of desktop publishing on personal computers, there is another way that is quick and easy, and produces top quality results. The desktop publishing technique has several advantages over other methods. It allows you to design the panel

electronically, so changes are easy to make without the hassle of physically changing things. This way you can get the layout exactly the way you want it, before "cutting metal." The only limit to the degree of detail and complexity is your imagination: You can put whatever you want on the panel, including graphic images. If you can do it on the computer, you can put it on a panel.

As a practical matter, a printed copy of the panel layout can be used as a template for drilling holes and making cutouts on the physical panel. This assures proper alignment and location of switches, jacks, indicator lights, etc.

This article describes the desktop publishing method and the resolution of the pitfalls

the author encountered. Hams who build electronics projects are encouraged to "dress them up" with professional-looking panels and labeling.

Making a Panel

I recommend making an initial rough pencil layout of the panel. Make sure that you plan for all the switches, control functions and the like that the project either does have, or may have in the future. Leave room for additions or embellishments to your project. See Photo D for an example of a rear panel showing jacks for just such future embellishments.

Use your favorite desktop publishing software to make a full-size layout of the panel.

Photo A. The "CONSTANT CURRENT," panel made with a 9-pin dot matrix printer.

Photo C. The "roll on" technique recommended for application of the film.

Photo B. Front panel of "FREQUENCY MASTER," showing the computer-generated panel layout.

Photo D. The rear panel, showing provisions for "embellishments" as mentioned in the text.

Photo E. A painted panel with the film in place, ready for cutting to shape and drilling.

Make sure you have it the way you want it: The finished product will be exactly like that in the computer. Print out a copy of the finished layout to be sure it is OK. For best results, I recommend a laser printer, but 9-pin dot matrix printers can also produce quite good products. The "CONSTANT CURRENT" panel shown in Photo A was done with a 9-pin dot matrix printer.

Take your final artwork to your local copy shop. Make a copy on paper, and a copy on transparent stick-on film. The film used for making the "FREQUENCY MASTER" panel shown in Photo B was called Graphic Applique Film. It was the brand offered by my local copy shop, and should be available widely. It works well, without stretching or distortion during application.

I recommend completing all the metal work and painting before applying the film.

This results in the best-looking panel, but it also requires careful alignment of the film before sticking it in place. The film sticks tightly and can pull the paint off if it is lifted for realignment. Use the paper copy for drilling and cutting the panel. Rubber cement works great for sticking the paper copy to the metal panel. I found out the hard way that "100%" size on most copy machines is not actually 100%. But if you use the paper copy, it will be the same size as the film you will be applying later. When cutting the panel from the material you use (I used double-clad PCB here), leave a small tab on one end. I left about 3/4" on the end of the "FREQUENCY MASTER" panel (Photo B). This tab serves as a place to stick the film down while aligning it with the panel. Cut off the tab after applying the film.

Alternatively, the film can be applied be-

fore drilling and cutting the panel. If you use this technique, sharp drills and cutting tools must be used to prevent damaging the film during that operation.

Apply the film by aligning it carefully and sticking it down to the tab. Bend the film so that the stiff backing will "unroll," and rub the film down with your finger as it comes in contact with the painted panel. See Photo C. Apply only a small area at a time. Make sure all the small air bubbles are rubbed out as you go. Any trapped air will not come out later. It is important that the air be rubbed out as the film is applied.

The edges of the film can either be rolled around the edges of the panel and stuck to the backside, or trimmed neatly to the panel edges with a sharp X-acto knife. I recommend putting a thin bead of white glue around the trimmed edges to prevent clumsy handling from lifting the film during use.

The film needs no protection for normal handling—the lettering seems to be durable. Once the film is applied to the painted panel it is ready for use.

Using the desktop publishing technique produces craftsman-quality labeling for home-brew electronic projects. The results are comparable with rub-on lettering and India ink, and can be achieved with considerably less time and effort. I recommend this technique for all who enjoy building electronic projects.

Link Communications RLC-II Repeater and Linking Controller

RLC-II Features:

- (1) Full Featured Repeater port
- (2) Linking Full-Duplex ports
 - Linking ports capable of operating as stand alone repeater ports
 - Separate ID's, Time-Out Timers, Hang timers, and Courtesy Beeps
- (4) Analog Lines Programmable for Temperature and Voltage Readings
- (4) Input Lines for Contact closure Readings
- (8) Output Lines for control of external peripherals
- Clean and Understandable Voice Synthesizer with 400+ words
- All Ports have both COR and PL inputs allowing off site access changes
- DTMF Access from ALL Ports
- 2400 Baud Serial Port allows remote programming of the RLC-II
- Optional Full Duplex Autopatch with 200 Number Dialer Only \$199.95 plus s&h
- Optional 19" Steel Rack Mountable Enclosure Only \$100.00 plus s&h
- (20) Time Scheduler Slots with Hourly, Daily and Weekly Events Voice Time of Day Clock
- Complete Remote Programming using DTMF Tones
- Multiple Password Priority Assignable to each command
- All Commands can be renamed from 1 to 6 digits in length
- Independent DTMF mute function can be assigned to all ports
- Doug Hall RBI-1 Remote Base control of Kenwood Radio support

ONLY \$599.95 plus s&h

Home-Brewing Your Own RF Filters

Radio frequency filters are inductor-capacitor networks that pass one band of frequencies, while rejecting all other frequencies. Hams use RF filters in a wide variety of applications: keeping harmonics at the transmitter, preventing out-of-band signals from getting into the receiver, etc. There are four basic types: low-pass filters (LPF), high-pass filters (HPF), band-pass filters (BPF) and rejection filters (called notch filters when the rejection band is narrow, and bandstop filters when the rejection band is wider).

The LPF and HPF frequency responses are shown in Figures 1A and 1B, respectively. In the LPF (Figure 1A), all signals from DC to some cut-off frequency (F_c) are passed, but above F_c the response falls off to the

point where there is little signal passing. The cut-off frequency is usually defined as the point where the frequency response falls off -3 dB from the in-band response. The HPF characteristic is shown in Figure 1B, and is exactly the opposite of the LPF: It rejects all frequencies below its cut-off frequency, while passing all frequen-

Table 1.						
No. Elements	Ripple (dB)	C1	C2	L1	L2	L3
5	1	3473.1	3473.1	16.99	23.88	16.99
5	0.1	4364.7	4364.7	9.126	15.72	9.126
5	0.01	4153.7	4153.7	6.019	12.55	6.019

deed. But if you use tables of values for "normalized" generic filters, then the job becomes a lot easier . . . and certainly falls into the "easily do-able" category. I recently tried my hand at a number of RF filters for different purposes, only some of which are related

HPF and LPF designs with overlapping cut-off frequencies of 3,000 kHz or so (the exact frequency was not critical). Second, I needed an 8,000 kHz LPF for a small 40 meter 1.5-watt power oscillator that I was building. Finally, I needed an LPF that would reject the AM broadcast band, while passing LF/VLF signals. For these projects I turned to the *ARRL Handbook* for the normalized tables. The circuits are found on page 2-51 in the 1993 edition, while the tables are found on pages 2-51 and 2-52. Figure 2 shows the basic LPF circuit, while Figure 3 shows the HPF case (both use the part designations found in the *ARRL Handbook*).

The tables give the values for the normalized case where $F_c = 1$ MHz; the inductances are given in microhenrys (μ H) and the capacitances in picofarads (pF).

Example: The Low-Pass Case

In this example let's look at my 3,000 kHz LPF. It was used in a sweep signal generator that I designed for the AM broadcast band, and for common AM IF frequencies (e.g. 455 kHz). I needed it to facilitate a project that I am working on: a super AM DXer's receiver (sorry, no details as yet). A portion of the normalized 1 MHz data from Table 20, p. 2-52, is shown in Table 1.

The number of elements in the complete table varied from three to nine (odd numbers), but because this filter has two capacitors and three inductors, only the five-element data is reproduced (see the book for the complete table, as well as those for the HPF and other designs). The ripple data refers to the maximum ripple in the passband of the filter, and is expressed in decibels (dB). I selected the 0.1 dB figures.

The table data are normalized to 1 MHz, so to find the values of inductance and capacitance needed for the actual filter divide the values in the data table by the frequency in megahertz (MHz). To find the values for my 3,000 kHz (i.e. 3 MHz), 0.1 dB ripple LPF I divided the *ARRL Handbook* values by three:

$C1 = C2 = 4364.7/3 = 1454.9$ pF; $L1 = L3 = 9.126/3 = 3.04$ μ H; $L2 = 5.24$ μ H.
C1: 1454.9 pF
C2: 1454.9 pF
L1: 3.04 μ H
L2: 5.24 μ H
L3: 3.04 μ H

The coils are relatively easy to come by: Wind them on Amidon Associates [2216 East Gladwick Street, Dominguez Hills CA 90220; phones: (voice) 213-763-5770, (Fax) 213-763-2250] coil forms. The T-50-2 (RED) cores have an AL value of 49, and op-

"The filter projects turned out so well that I am convinced it is another case of . . . the contriving of contrivances is a game for all."

cies above F_c . Note that these curves are a bit idealized; real RF filters are not so smooth either in the passband or outside it.

If you start "raw" and design your own filter, then the task is daunting in-

to ham radio, but all of which illustrate the principles involved. You can also use the same method to design filters for your own purposes.

I had several projects in mind when I built some filters. First, I needed both

Figure 1. A) LPF frequency response; B) HPF frequency response.

Figure 2. LPF circuit.

Figure 3. HPF circuit.

erate from 2 to 30 MHz, while the T-50-15 (RED/WHT) have an AL of 135 and operate over 0.1 to 2 MHz. In practice, I found that 3 MHz was not unreasonable for the -15 cores, so I opted to use them. Applying the formula below gave the number of turns:

$$N = \sqrt{L_{\mu H} / A_L}$$

L1, L3: 3.04 μ H, 15 turns, T-50-15 (RED/WHT)
L2: 5.24 μ H, 20 turns, T-50-15 (RED/WHT)

The capacitors are another matter. Where in blazes do you get a 1454.9 pF capacitor? Well, one solution is to use a 0.0015 μ F (1,500 pF) and live with the slight frequency error. I did this and found that the filter had a cut-off frequency only slightly lower than

3,000 kHz, and it was acceptable. Otherwise, it is possible to select standard value capacitors that in some series or parallel combination total 1454.9 pF, or something close to it. For example, 75 pF, 560 pF, and 820 pF add up to 1455 pF, and all are easily available values.

The capacitors used in the filter should be NPO disk ceramic, silvered mica, or polyethylene. I bought several dozen of all types recently from Ocean State Electronics [P.O. Box 1458, 6 Industrial Drive, Westerly RI 02891; phones: 1-800-866-6626 (orders), 401-596-3080 (inside RI), or 401-596-3590 (Fax)]. Ask them for their catalog . . . you'll find a lot of ham building parts that you thought were "history" because other parts distributors no

longer carry them.

Another approach is to use a combination of fixed-value and trimmer capacitors in the filter. This is a viable approach if you have a sweep generator and oscilloscope to align the filter, but can be a "bear" if you don't. A procedure for alignment of such filters is given in Hayward and DeMaw's *Solid-State Design for the Radio Amateur* (an ARRL publication).

The filter projects turn out so well that I am convinced it is another case of " . . . the contriving of contrivances is a game for all."

Book Note

One of my publishers has moved, and has also added an "800" number

for credit card orders. HighText Publications is owned by Harry Helms and Carol Lewis. Their address is: 125 North Acacia Avenue, Suite 110, Solana Beach CA 92075; phones 619-793-4141 and 4142. Credit card orders are handled by IPG at 1-800-888-4741. They publish my *Receiving Antenna Handbook* and *The Art of Science*, as well as Harry Helms' books *All About Ham Radio* and *Shortwave Listening Guidebook*.

They now claim to be the biggest technical publisher west of Pacific Coast Highway (or, is that the only publisher west of . . . ?), and to have sales greater than the combined profits of IBM and General Motors. Helms, you're dangerous.

AMATEUR TELEVISION

SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. Others may be retransmitting weather radar during significant storms. If it is being done in your area on 70 CM - check page 413 in the 91-92 ARRL Repeater Directory or call us, ATV repeaters are springing up all over - all you need is one of the TVC-4G ATV 420-450 MHz downconverters, add any TV set to ch 2, 3 or 4 and a 70 CM antenna. We also have downconverters and antennas for the 900 and 1200 MHz amateur bands. In fact we are your one stop for all your ATV needs and info. Hams, call for our complete ATV catalog - antennas, transceivers, amplifiers. We ship most items within 24 hours after you call.

Houston TX 77083

SSTV From Space

Only 10 days after the launch of AMSAT-OSCAR-6 in October 1972, Don Miller W9NTP wrote a letter to the editor of the *AMSAT Newsletter* describing his efforts with WA9UHV to send slow-scan television images via the new satellite.

In his letter Don described systems that included equipment that might be found in a ham radio museum today, but 20 years ago represented state-of-the-art gear. HF transmitters with transverters and home-brew video samplers and modulators provided uplink signals, while more home-brew equipment was used to view the black-and-white images sent through the Mode "A" (2 meters up and 10 meters down) transponder. These pioneering efforts have provided inspiration for today's video experiments and some exceptional possibilities for later this decade.

In his mid-seventies book, *OSCAR Amateur Radio Satellites*, Stratis Caramanolis recounted efforts by DL8AT and OE3KMA to send SSTV pictures via the Mode "B" (70 cm up and 2 meters down) transponder on AMSAT-OSCAR-7. The year was 1976 and eight-second, black-and-white pictures were still the standard. These efforts led to additional image transfer techniques including facsimile (FAX) transmissions by DL0VB and others.

During the 1980s emphasis was placed on the purely digital modes like AX.25 packet. Today we have

several digital-only satellites in orbit, capable of providing worldwide store-and-forward services. Sending image files via these electronic bulletin boards in the sky has become common. Real-time image exchange via satellite declined, but thanks to advances in inexpensive digital interface techniques and individual efforts, SSTV operation is again gaining popularity.

SAREX and SSTV

Dr. Tony England W0ORE took the Shuttle Amateur Radio Experiment (SAREX) equipment to orbit on the shuttle *Challenger* in August 1985. Part of the ham gear included a modified ROBOT 1200C scan converter for SSTV. The image-control software on the shuttle supplied automatic sequencing, providing two red-filtered frames (8 sec.), one green and one blue; a low-resolution color frame (12 sec.); and a high-resolution color image (36 sec.). Many stations monitored the signals using home-brew SSTV systems or new and expensive ROBOT equipment. Others simply recorded the warbling tones in hopes of someday decoding the cryptic sounds and viewing the pictures.

Further experiments with SSTV from the shuttle continued on missions STS-37 and STS-50. The equipment will be carried on STS-56 and other future flights.

In addition to sending pictures earthward, the shuttle apparatus can also receive and display images sent from earth-bound hams. During Tony England's flight, a picture of the astronauts' wives was sent up to space and displayed on one of the monitors

Photo A. A 36-second ROBOT color image of Tony England W0ORE on the Space Shuttle Challenger—August 1985.

located in the Aft Crew Station. The picture was stored and sent back to earth a few minutes later. During STS-50, schools with suitable SSTV gear sent pictures of the students up to Dick Richards KB5SIW and the other ham crew members on board the *Columbia*.

There are advantages and disadvantages to shuttle-based SSTV operation. On the plus side, the signals are sent via 2 meter FM transceivers. Signals are strong and color errors caused by frequency shift experienced using SSB are not a problem. The greatest disadvantage is the length of time available for picture exchange. Shuttle passes are usually very short, 10-15 minutes. The ROBOT equipment is capable of a 72-second mode, but images are usually sent in the 36-second mode to allow the exchange of as many pictures as possible. The ROBOT gear is also limited to those ROBOT

modes hard-coded in the scan converter.

SSTV and the PC

PC-SSTV interfaces have lagged behind those for other machines like the Amiga, and only a few dedicated hams have been able to buy a ROBOT 1200C at over \$1,000 for computer-less operation. Although the Amiga computer and appropriate interface cost less than a ROBOT, those already heavily invested in PC-compatible machines (most of us) don't consider either a viable alternative.

Early attempts to provide SSTV support on PCs required the use of the cassette port to input the tones. Rough, blocky, black-and-white pictures could be seen from the eight-second format frames on monochrome monitors. The software was crude and the results poor. Better interfaces, faster machines

Photo B. A 36-second ROBOT color image of Ken Bowersox, Carl Meade and Dick Richards KB5SIW on board the Space Shuttle Columbia (STS-50)—June 1992.

Photo C. Dave WB6LLO poses for a 72-second ROBOT color picture sent via AMSAT-OSCAR-13.

and improved video were needed. Recent offerings have certainly helped.

For the satellite enthusiast looking to get results without a significant investment, there are two inexpensive PC-SSTV interfaces available.

The first is the Viewport VGA from A & A Engineering. This unit was described in a construction article by J. R. Montalbano KA2PYJ in the August 1992 issue of 73. A complete kit from A & A Engineering (telephone: 714-952-2114) sells for \$169. This unit transmits all the ROBOT modes through 72-second color and receives ROBOT plus Scottie and Martin formats. Recent modifications also allow operation with a new FAX mode defined by Ralph Taggart WB8DOT in the February 1993 issue of QST. The Viewport VGA is an external interface box that connects to the PC through the printer port.

The second recent offering for PC owners looking for a way to do SSTV is the Pasokon-TV interface card and software. The card uses a slot in the PC (286 or better) and provides full transceive operation with all of the popular SSTV modes, including ROBOT, Scottie, Martin and others. The kit costs \$200 and is available from John Langner WB2OSZ at (508) 256-6907.

Hamsat SSTV

Most SSTV operation via satellite is currently on AMSAT-OSCAR-13 using ROBOT 72-second color. Activity is usually heard during times when the satellite signals are strongest. This is when the satellite's antennas favor the earth. Dave WB6LLO promotes an informal SSTV net for weekend activity via modes B and J (2 meters up and 70 cm down). The "B" downlink is 145.960

via satellite the problem of "skip" is not present. In fact, due to the nature of full duplex satellite activity, you can monitor your own signal as it is being heard by other ground stations. The only disadvantage to SSTV via A-O-13 is the noise. Many stations do not have antenna systems for noise-free copy of SSTV, and since SSTV is a 100 percent duty cycle mode and should not be run at full power on the transmit side, signals are not like the

gest problems encountered are the effects of Doppler shift, causing color changes as frequencies shift, and interference from 15 meter stations not aware of the satellite operation. SSTV gear used by both stations has included the AEA AVT Master Amiga Video Terminal with Commodore Amiga computers. Although superior results might be possible with newer SSTV modes, the short passes have yielded more pictures with the 36-second ROBOT format.

Full-Motion Video

Standard fast-scan television (FSTV) operation via satellite is not currently being considered. The bandwidth required exceeds that available on most bands allocated for amateur radio satellite use. The FSTV experiments to uplink video to the Space Shuttle require FCC permission for the participating stations to send 6-MHz-wide signals to space. The 70 cm uplink band is normally only 3 MHz wide.

For now SSTV is the best way to get images across without using the digital store-and-forward satellites. In the future, work on video-compression techniques will allow nearly full-motion video via hamsat using special modems and digital data at 9,600 to 56,000 bps.

"The advantage of satellite SSTV is the lack of interference. While coverage is worldwide, the congestion is much easier to take than on HF."

MHz and the "J" downlink is 435.980 MHz.

The advantage of satellite SSTV is the lack of interference. While coverage is worldwide, the congestion is much easier to take than on HF. The odds of a station ruining a good picture by tuning up or talking over it are very small. Unlike the shortwave bands where everyone cannot hear each other on a particular frequency,

blockbusters sometimes heard on 20 meters. Consistency of the signals and lack of interference balance the equation.

A-O-13 is not the only satellite passing SSTV signals in the sky. RS-12 is as well. Rick VE4AMU and WA2KUK have been trying ROBOT 36-second color via the mode "K" (15 meters up and 10 meters down) transponder. The big-

NEW

DSP From JPS

NEW

The NRF-7

The new NRF-7 is a medium priced DSP product which provides great flexibility in audio processing. Modes available include atmospheric (white) noise reduction through adaptive peaking; spectral multi-tone notch filtering; notch & peak combined; wide (2400 Hz) and narrow (1800 Hz) SSB filters, with and without spectral notch; wide (500 Hz) and narrow (250 Hz) CW filters with selectable center frequency; and a 500 Hz wide

DATA filter centered at 2200 Hz. Since these filters all operate in real time, they can be used for Break-in CW or AMTOR. Note: noise reduction by adaptive filtering reduces noise by dynamically reducing the bandwidth and is not effective against impulse-type noise. **Only the NIR-10 uses spectral subtraction to eliminate impulse noises as well as atmospheric noise, while retaining the full audio bandwidth.**

Only: \$249.95

The NIR-10, the standard in DSP Noise Reduction, still only \$349.95.
For eliminating carriers & other tones, the NF-60, still only \$149.95.

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

Having been involved in radioteletype for many years, it's easy to lose sight of the simple questions with complex answers posed by the newcomer. To wit: Timothy S. Kraus KC4ZGP, of Warner Robins, Georgia, writes that "Lately, I've been watching hams converse in 60 wpm Baudot TTY. I got to thinking, I'd like to talk to folks out there. Do you know where I can find a surplus TTY keyboard? I have the receive side—my Microdec MD-100—I just need a keyboard. I don't have a computer and I hope I won't have to buy one because RTTY keyboards are getting rare."

Well, Tim, there are at least three ways you can go with this. First off, let's define a "RTTY keyboard." The keyboard attached to classic teleprinters such as Model 15s, Model 19s, and Model 32s, is an electromechanical conglomeration of levers, gears, and contacts. It runs both off the electrical circuit built into the machine and via a gear driven by the motor which powers the unit. The rotation of this gear is critical both to move the levers and to provide the timing needed for

the pulses. Thus, an isolated keyboard, without a machine, is relatively useless.

Next up the scale would be a self-contained Baudot keyboard. Using a Programmable Read Only Memory (PROM) or a diode matrix to encode the five level pulses, such a keyboard is a reasonable do-it-yourself project. Over the past 10 years this magazine has carried any number of such construction projects. A search of the 73 indices should turn up a few that you might look at. Trouble is, the blank keyboard used in such projects is becoming a scarce animal. James Electronics, among others, used to have one that was easy to use. Radio Shack used to, but no longer does, to my knowledge. You may be in trouble here in terms of obtaining the needed parts.

The third solution is the one you dread, getting a computer. I know, it seems like overkill. But a small computer, such as a used VIC-20, C-64, or Radio Shack Color Computer, should be available used for well under, well under, a hundred dollars. With suitable programming, any of them would do just fine.

The bottom line is to look around, see what's out there in your area, and

go for it. Whatever you do, why not write it up and share it with the readers of this column, and this magazine? We look forward to hearing from you.

Another letter arrived from Martha Nelson N3MHD, in Milton, Pennsylvania. She tells us that she has been "playing for about 10 months at a packeteering computer. For fun, I bought a 128K Tandy (color computer) . . . I use a Packard Bell (and) KAM for my communications. However, I would love to hear about your experience with the CoCo."

It really hurts me to say this, but you've bought an orphan. An orphan I have loved, an orphan with great potential, a very capable orphan, but an orphan nonetheless. You see, when the first CoCo came out, I was right there in the store, plunking down my cash almost before they unloaded the truck. I had my CoCo 2 running an 80 x 24 display, multiple disk drives, modem, and even multitasking under OS9. When Tandy Radio Shack introduced the CoCo 3, with more memory and better capabilities, we thought, at first, that this was to be an exciting new line. But as they emphasized the PC-compatible line they first neglected, then orphaned, the CoCo.

There are still support groups around, and there are an awful lot of these machines in users' hands. A very active SIG (special interest group) may be found on the Delphi computer network. There may be files elsewhere as well; I just can't find them. Person-

ally, I would use the CoCo as a dedicated terminal in front of a multimode controller, or use one of the available programs to run it in simple RTTY or packet mode. It is usable; it's just going to take some work. I do wish you luck, and I look forward to hearing about your progress.

Several of you have asked for circuits to power your teleprinters. The power supply used supplies a constant current in a loop, normally 60 mA or 20 mA, depending on the machine. At any rate, Figure 1 is an example of one such RTTY loop, which uses transistors as current-controlling devices. This is a good place to start, neither too simple nor too complicated. Maybe next month we will look at another circuit.

We've kept things basic this month, but that is not always the case. I look forward to hearing from you, each and every one of you, to let me know what you want to read about in "RTTY Loop." Reach me by mail, at the above address, or through E-mail on CompuServe (ppn 75036.2501), Delphi (username MarcWA3AJR), or America Online (screen name MarcWA3AJR). The software disks, RTTY and archiving, remain available as well. Each collection, two of RTTY programs and one of archiving programs, may be yours by sending me a high density disk sufficient for 1.3 Mb each, \$2 per disk sent, and a self-addressed stamped disk mailer. Be sure to indicate which collection you would like.

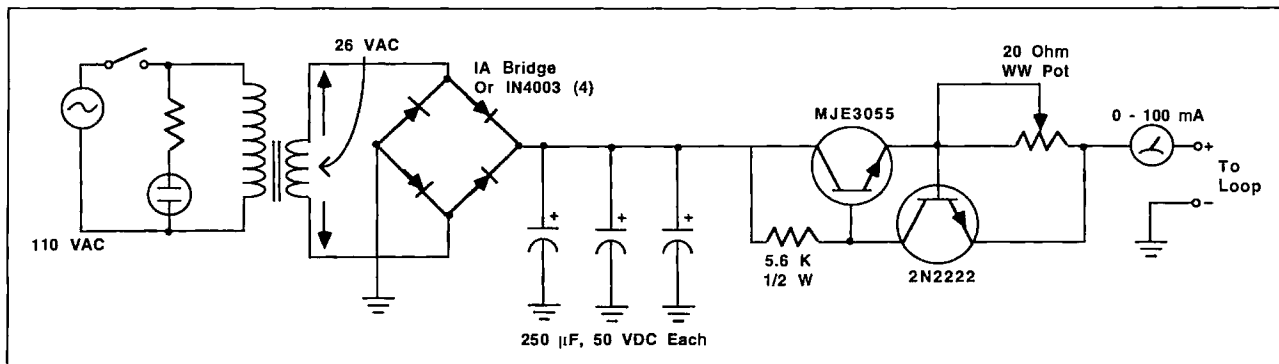

Figure 1. A circuit to power a teleprinter, using transistors as current-controlling devices. The power supply used provides a constant current in a loop, normally 60 mA or 20 mA, depending on the machine.

Teeny-Weeny T's

Newcomers to amateur radio direction finding contests often ask what special transmitters they must obtain to get in on the fun. Actually, the "fox" in a foxhunt or T-hunt, as these events are called, has it easy from an equipment standpoint. Most times, a handie-talkie or a mobile transceiver is all it takes. With enough battery power to last through the event and a source of audio (your voice or some sort of tone box), you're ready to set out in search of a hiding spot.

But the creativity of ambitious hiders sometimes demands special equipment. Last year in Albuquerque, New Mexico, T-hunters puzzled for a long time before they figured out that the hidden T was inside a cola can on a picnic table. On other hunts, this micro-T has been hidden in a hole in the bottom of a fireplace log, buried under a plant, and secreted in a cream cheese container under a rock.

Usefulness of a subminiature transmitter is not limited to competitive foxhunts. Almost every month I receive requests for tiny radio beacons for unusual purposes, ranging from keeping track of coon hounds to motorcycle theft deterrence. Some of these ideas are practical, others aren't.

There have been a few articles in hobby magazines with designs for fly-weight emitters, but they usually are lacking in stability, performance, and ruggedness. That's why I was delighted to encounter Ken Bauer KB6TTS and his radio retrieval devices.

Figure 1. Parts side etch (a), rear side etch (b), and feed-through hole locations (c).

Radio Direction Finding

Where's My Glider?

KB6TTS is an RF engineer at a Southern California aerospace company, with 10 years of experience working with transmitter and receiver circuits. In his spare time, he flies model gliders in the nearby deserts. These 7-foot wingspan craft can travel up to five miles in a typical flight if there are good "thermals" in the air.

Locating his models when they land out of visual range is a frequent and potentially expensive problem, so in the early 1980s Ken started experimenting with radio beacons for recovery.

In the model glider world, every additional gram of weight and ounce of drag is undesirable. Ken's latest glider beacon weighs only 2 grams, not counting the antenna and battery (Photo A). That's about a quarter of an ounce! With a 2-gram 3-volt lithium coin cell (#1225), it puts out a couple of milliwatts peak for about 48 hours. With a larger coin cell (#2032), it can achieve up to 8 milliwatts and transmit for a week.

This long battery life is due in large part to the low transmit duty cycle. A CMOS timer keys the transmitter for 100 milliseconds each second, giving short beeps in Ken's BFO-equipped receiver.

For more RF output power, which is usually desirable on T-hunts, use a standard 9-volt alkaline battery. This gives 25 to 50 milliwatts, but requires different biasing resistor values. The alkaline battery will last a week or more in the pulsed mode.

For glider recovery, the 222 MHz (125 centimeter) ham band is better than 2 meters. High gain beams for the receiver are smaller and there is less broadband noise from Santa Ana winds in the desert to mask the weak signal. Ken's transmitter can be built for either band by proper choice of crystal and tuned circuits.

The KB6TTS beacon board measures only 1.25" by 0.5", small enough for two to fit side by side on an Elvis stamp. Figures 1a and 1b are etch patterns. Front and rear etch are connected together at hole locations shown in Figure 1c. Figure 2 shows the parts placement.

Figure 3 is the schematic of the RF and pulsing circuits. Component values are for 2 meters. For the 1-1/4 meter band, change C2 to 47 pF, C4 to 22 pF, and C6 to 10 pF. Y1 will be 74 to 75 MHz. For operation with a 9-volt supply, change R1 to 10k, R2 to 5.1k, and R4 to 22k.

Ken's design is straightforward and reproducible. "Very hot RF transistors are needed for the unit to work well at low voltage and provide plenty of energy at the third harmonic of the oscillator," he says. "The Motorola MM-BR951L is a good choice because it's

Photo A. It's not hard to find hiding places for these little hidden T's, shown with three options for battery power. Dig-Key stocks the battery holders. Use quarter-wavelength wires as antenna and radial.

inexpensive and has gain up to 8000 MHz." "Q1 forms a Colpitts oscillator with the crystal, C1, and C2," he continues. "The crystal sees the combined capacitance of C1 and C2 as its 20 pF load and itself looks inductive as these elements form the main frequency control tank. L2 prevents the circuit from oscillating on the fundamental frequency of the crystal and keeps it in the overtone mode. The trick is that the oscillator will work only on frequencies where its emitter sees capacitance to ground. The combination of L2 and C2 must be such that they look capacitive at the overtone frequency but inductive at the lower fundamental frequency, thus preventing oscillation there."

Tank circuit L1/C4 is tuned to the transmitter output frequency, making Q1 an oscillator/triplet stage. Q2 is a buffer that amplifies the oscillator output and isolates it from load variations at the antenna. U1 pulses the Vcc supply to Q1 and Q2 with on and off time periods set by R5, R6, and C8. Change these components as you wish to give the right pulsing rate and duration for your application. It is important to use the CMOS version of the 555 timer to maximize battery life.

The crystal is a third overtone type at 2 meters and fifth overtone at 1-1/4 meters. It should be specified for 20 pF load capacitance, series resistance not more than 60 ohms, and frequency tolerance of 25 parts per million or better. Ken gets his from International Crystal Manufacturing (ICM), Oklahoma City, Oklahoma.

Pinhead-Size Parts

If your idea of project-building is dropping component leads through holes in a nice big circuit board and fastening them down with a soldering gun, you will need to change your ways for this project. Making an "Agent 007 size" transmitter calls for the same technology used to make today's pocket-size dual-band handie-talkies. All capacitors and resistors are chip components except R5, which is 1/8-watt carbon. The transistors and IC are in surface-mount packages.

This is definitely not a beginner's project. If you have successfully built a few circuit boards and know your way around VHF RF circuits, you should be able to build and adjust this little rig. Otherwise, seek help from a local technically-inclined ham.

Surface-mount construction may seem a bit scary, but it just means acquiring a few new skills. Set your soldering gun aside and use a fine-tipped iron, 18 to 25 watts. You will also need steady hands, a strong light, a low-power magnifying lens, and a pair of fine-point tweezers.

Once you get the hang of it, soldering a component onto the board is not difficult. Pick up the part with tweezers and "wet" one terminal using the soldering iron and a tiny amount of solder. Use the tweezers to hold the part down on the board in its place, then momentarily touch the iron to the pre-tinned pad to flow the solder and secure the component. Then tack down its other leads, being careful not to overheat the part so that it shifts position on the board.

Bare circuit boards are available for

Figure 2. Parts locations for the KB6TTS beacon transmitter. All components except C10 are on the front side.

\$10 each from KB6TTS. Ken is not selling parts kits, but he will build complete transmitters to order as his spare time allows. For information and prices, send a self-addressed stamped envelope to Airtex, 2306 Turquoise Circle, Chino Hills, CA 91709. If you're into flying models, ask for his info sheet that gives tips on aircraft transmitter mounting and retrieval techniques. As usual, here's the disclaimer: These offers are not warranted by 73 Amateur Radio Today or by me.

Q1 and Q2 are available from Motorola distributors. One that sells to individuals is Newark Electronics. Newark has over 200 branch offices across the USA and Canada. Call the main office in Chicago at (312) 784-5100 to obtain a catalog and get the phone number of the nearest branch.

To order a crystal from ICM, call (800) 426-9825. Specify the crystal frequency (transmitter output frequency divided by 3) and part number 471393 for 2 meters or 472393 for 1-1/4 meters. These ICM part numbers

determine the mode, load, series resistance, tolerance, case, and leads.

The remainder of the parts are available from Digi-Key Corporation, PO Box 777, Thief River Falls, MN 56701, phone (800) 344-4539. The resistors are Panasonic thick-film, 1/10-watt, series 0805. The capacitors are Panasonic multilayer ceramic. C3, C8, and C9 are type X7R, and the remainder are type NPO, for low drift. L2 is Toko type 32CS.

L1 and L3 are made from AWG 32 enameled wire, wound over a 0.06"

diameter drill bit, then slipped off and soldered onto the board. Start with the turns close spaced. You will spread the turns as necessary to tune each stage.

Keep Our Spectrum Clean

The primary goal of tune-up is to peak up output on the transmit frequency and minimize output on the fundamental and all other harmonics of the crystal. A spectrum analyzer is the ideal tune-up instrument, but most of us don't have one at home.

TRIPP LITE DC POWER SUPPLIES: YOUR KEY TO GREAT COMMUNICATIONS!

According to 73 Magazine,
it's performance that
"never misses a beat."

Tripp Lite gives you:

- Great looks and high performance
- Crowbar protection
- Excellent regulation and line noise isolation
- Units available from 3 to 60 amps
- Competitive prices

PR Series DC power supplies are ideal for powering practically everything in your ham shack, including low band rigs, 2 meter and UHF radios.

Sample a unit today!

CIRCLE 390 ON READER SERVICE CARD

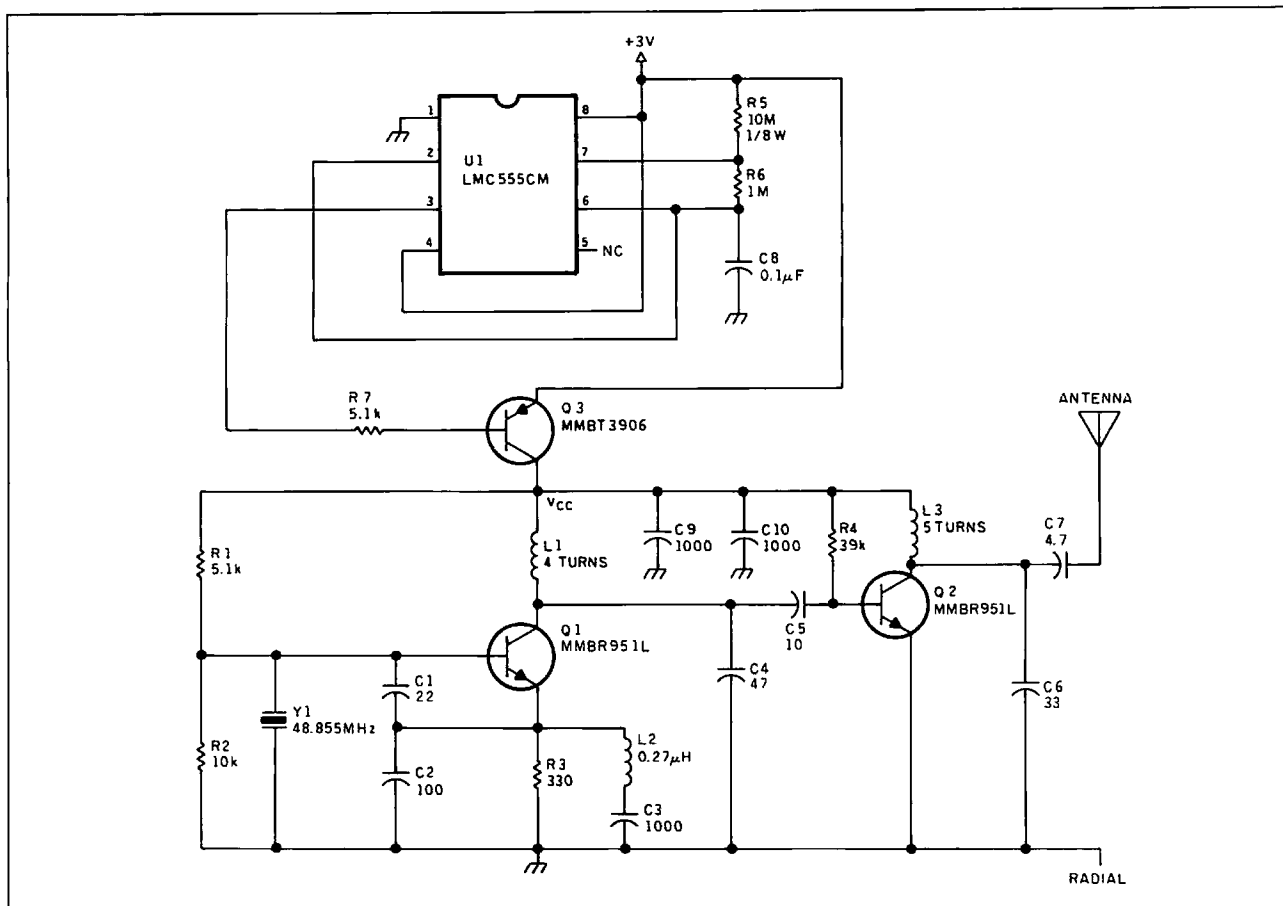

Figure 3. Schematic of the tiny transmitter as built for 146.565 MHz, the Southern California T-hunt frequency. Unless otherwise specified, capacitances are in picofarads. See the text for component changes for the 222 MHz band and for 9V power supply.

With a bit of patience, you can substitute the S-meter of a wide-range receiver.

As an example, the output of a 146.565 MHz unit should be checked at 48.855, 97.710, 195.420, 244.275,

and so forth, tuning to minimize all spurs and maximize the 2 meter signal. Tune-up is easiest with continuous output, so jumper the collector and emitter of Q3 during this process. Whether you use an analyzer or re-

ceiver, connect the mini-T's output to the indicating instrument through a resistive step attenuator, so you are measuring the true output instead of direct radiation from the stages.

Ken's board has no provisions for

ID or modulation. You will want to add these as appropriate for your application. Many CW keying circuits have been published, and they can readily be adapted to key the Vcc line of this rig.

DSP Power for Amateur Radio

- GREAT FOR HF, VHF, UHF, EXPERIMENTATION, ETC.
- CONNECTS TO THE PAINTER PORTION OF A HAM RADIO
- PROFESSIONAL AUDIO WITH A DANCE-BEAT TAILORING
- EXTENSIVE POWER HANDLING NOTCH AND ARE TRAP FILTERS
- INSTANTLY ELIMINATES NOISE ENHANCE DESPOT ALIENS
- RECORD AND PLAYBACK THREE DIFFERENT DIGITAL FILTERS
- APPLY POWERFUL DSP TIME AND FREQUENCY TECHNIQUES
- HIGHEST PERFORMANCE DSP ARCHITECTURE YOU CAN BUY
- LIGHTNING-FAST HIGH RESOLUTION COLOR SPECTRAL ANALYSIS
- SOFTWARE EXTENSIBLE FOR UNLIMITED POSSIBILITIES
- MUCH MORE! 30 DAY MONEY BACK GUARANTEE!

DSP-120 kits & systems start at **\$99**

"Easily the best DSP our club has seen. We mixed a SSB, RTTY, CW, and some interference, to the ear it sounded terrible, the DSP-120 filters out everything but the desired mode (SSB, RTTY, or CW). In fact, we can quickly identify, filter, and listen to one of the RTTY tones. Very impressive!"

SCARED OF THE CODE?

IT'S A SNAP WITH THE ELEGANTLY SIMPLE MORSE TUTOR ADVANCED EDITION FOR BEGINNERS TO EXPERTS—AND BEYOND

Morse Code teaching software from GGTE is the most popular in the world—and for good reason. You'll learn quickest with the most modern teaching methods—including Farnsworth or standard code, on-screen flashcards, random characters, words and billions of conversations guaranteed to contain every required character every time—in 12 easy lessons.

Sneak through bothersome plateaus in one tenth of a word per minute steps. Or, create your own drills and play them, print them and save them to disk. Import, analyze and convert text to code for additional drills.

Get the software the ARRL sells and uses to create their practice and test tapes. Morse Tutor Advanced Edition is approved for VE exams at all levels. Morse Tutor is great—Morse Tutor Advanced Edition is even better—and it's in user selectable color. Order yours today.

For all MS-DOS computers (including laptops). Available at dealers, thru QST or 73 or send \$29.95 + \$3 S&H (CA residents add 7.75% tax) to:
GGTE, P.O. Box 3405, Dept. MS,
Newport Beach, CA 92659
Specify 5 1/4 or 3 1/2 inch disk
(price includes 1 year of free upgrades)

Various Gripes

This month, I'd like to address various small topics which keep cropping up, but none of which warrants an entire column by itself.

Those Darned Batteries

First of all, nickel-cadmium batteries. I've written a fair amount about them, and I've seen various contradictory articles. Frankly, I'm getting sick of the whole thing. Some say the "memory" effect exists, some say it doesn't. Some say that dischargers are a bad idea, others like them. My opinion, once and for all: It may be memory, it may be something else, but whatever you want to call it, NiCd packs don't work very well for very long. After six months or a year, you almost inevitably wind up with one or more weak or shorted cells. Just tonight I had to crack open two \$100 laptop computer packs, each manufactured about two years ago and bought and used only about eight months ago. In both of them, there were a few shorted cells alongside others which were fully charged. That has happened to just about all the NiCd packs I've ever owned, and I follow all the rules. I suspect that the true cause of the failures is charge imbalance.

What seems to happen is this: Because no two cells can be absolutely identical, some discharge faster than others, especially when sitting idle on the shelf. When the pack appears to need recharging, it really has some cells which are only partially discharged. When you charge it up, their higher resistance prevents the weaker ones from getting a full charge. Next cycle, it gets even worse because the weaker ones die even faster due to their having only a partial charge to begin with. Eventually, the weaker ones wind up getting reverse-charged by the stronger ones (during the discharge cycle) and they short out. End of pack. I've had some success with zapping them, but it requires opening the pack, and it doesn't always last.

I've never seen any literature regarding whether you should keep your packs charged or discharged between uses. In light of the above, it might make sense to leave them discharged. That way, they can't slowly sink down to uneven levels while sitting on the shelf; they're all pretty low anyway. I can't verify the wisdom of this approach, but it's a strong hunch. Perhaps that's why

they ship them discharged from the factory.

As for dischargers: Many people pooh-poo them, but they may be wrong. Did you know that Sony is now offering, for their video equipment, optional chargers which include automatic dischargers? Apparently, even *they* are admitting there's a problem with NiCds. I haven't tried a discharger, so I can't say for sure whether they actually work. Even if they can't fix a bad pack, at least they let you charge up your pack whenever you want to, ending the frustration of having only half a charge because you're afraid to charge up a partially charged pack.

I don't want to write about NiCds anymore. As I've said before, the only ones which have worked fairly well for me are those made by Sanyo. They seem to hold a charge much longer while sitting idle, and that may have something to do with it. Hopefully, the new nickel-metal-hydride cells or some other new kind of battery technology, such as the up-and-coming rechargeable lithium cells, will obsolete the old stuff once and for all. End of topic. Please.

Open Wide

If you've ever spent any time on the 20 meter band, you've heard squabbles arising over somebody with excessive bandwidth. Just yesterday I heard one such argument, including (and this is a direct quote), "I don't think my 50 watts could be that wide." Folks, your bandwidth has *nothing* whatever to do with how much power you are putting out. You could be running 100 milliwatts and still be 10 kHz wide!

We're all supposed to be no more than 3 kHz wide, unless we're running AM or FM. On AM, we can be 6 kHz wide, and on FM even wider. That's why FM is not allowed below 10 meters. Ten's a big band, so there's room for wider stations. The lower bands are just too small.

AM

There are some people who run AM on 20 meters. In fact, there's an entire net of them. Personally, I find the idea inconsiderate but, hey, they are allowed to do it, so until the rules change, we'll all have to live with it. Luckily, they tend to stick to one frequency, so it really isn't all that big a deal.

The problem is that most AM transmitters are far wider than 6 kHz! To stay within that limit, the audio response must go no higher than 3 kHz, just like on any other mode. Compounding the circumstance that most of these transmitters are very old, and have no filtering to prevent

them from being too wide, is the fact that many users go out of their way to get microphones with what they call "broadcast quality" sound. In other words, lots of high frequency response! Many AMers take a great deal of pride in sounding hi-fi (and say so on the air), while conveniently ignoring, and sometimes denying, the resulting bandwidths of their signals. Folks, you can't have the crisp, commercial-quality highs without the bandwidth.

SSB

But before it sounds too much like I have it in for AMers, which I really don't, let me say that plenty of SSBers also are too wide. There are several reasons, but the most common one is the over-adjustment of speech processors. Lots of hams, and especially DXers, turn them up to the point of pain. I've probably done it myself a few times, but it isn't hard to avoid. If you have an IF monitor button on your rig, plug in a pair of headphones and listen to what you're putting out. If it sounds overly peaky and distorted, back it down a little! If you don't have a monitor, have a friend listen up and down the band to see if you're within proper bandwidth limits. This works best from the range of a few miles, rather than from across the country. But even that is better than nothing. Above all, though, if people complain that you're wide, don't get defensive. Check it out; they may be right.

The reason high power is associated with excessive bandwidth is that it is really easy to overdrive a linear amplifier and cause signal-widening distortion. Using the amp's ALC line can help prevent it, but not completely. Some amps just aren't all that linear to begin with. But, a good clean amp with the right drive will be no wider than the signal driving it. And even a QRP rig can have excessive bandwidth if you let it.

There's another reason for SSB rigs' being too wide, and this one is no fault of the operator. While it is true that today's rigs have audio filters which roll off above 3 kHz, they don't have terribly steep skirts. In other words, some of the higher frequencies do get through. Most of the filtering action occurs at the SSB filter in the transmit IF stage.

SSB rigs have two adjustments, one for each sideband, which set the frequency of the carrier before it is suppressed in the balanced modulator. These frequencies are chosen to coincide with the filter skirts such that no opposite sideband or residual carrier energy get through the filter. Typically, the adjustments are trimcaps connected to crystals in fixed crystal oscillators. In older rigs which did not have IF shift or variable bandwidth tuning functions, adjusting the oscillators caused the entire rig to shift in frequency. Many newer radios shift the first local os-

cillator to track the carrier oscillator. (And you don't need digital synthesis to do it; heck, my old TS-120 did it with a PLL circuit, even though it had an analog VFO.) Doing that has the effect of changing the passband without detuning the radio, which is exactly what you want when you turn your IF shift or VBT control. What most people don't realize, though, is that it can happen in transmit as well as in receive.

Obviously, the IF shift control disappears in transmit. But what if the oscillator is off to begin with? If it is set too far toward the low end of the filter's response, the radio may radiate carrier or opposite sideband. If it is set too high in the response, there'll be lots of audio highs and the RF signal will be too wide.

Over time, these oscillators drift. If your rig is on frequency but the sound quality differs markedly between USB and LSB, you may have this problem. It doesn't take much more than 50 Hz drift to do it! Correcting it requires a frequency counter. If you have a sharp ear, you can make it better just by matching the sounds of the two sidebands while listening to background static. Don't expect them to be identical, though; the two carriers are coming at the filter from opposite sides of its passband, and no filter is perfectly symmetrical. By the way, the by-ear approach works best when only one sideband is obviously off. If they're both off, you have no way to know where they belong.

There are some people who deliberately set the carrier oscillators to make their rigs sound "punchy" and "hot." What they're doing, of course, is reducing the bass and increasing the highs. If you do it, you will annoy other amateurs and violate FCC rules with your wide-as-a-bam-door signal. It is far better to have the carriers set properly and then use a punchier microphone or a little speech processing to get the sound you want. It is possible to sound crisp and punchy within 3 kHz. Up to a point, anyway.

SSTV

SSTVers take a lot of flack from voice operators. Some lids go as far as causing deliberate QRM to those exchanging pictures. Often, I've heard cracks about "all that splattering noise interfering with us." In truth, SSTV tends to be a bit *narrower* than the allowed 3 kHz. The audio frequencies used to modulate the transmitter are carefully controlled, and they're sine waves. All in all, a much cleaner signal than what comes from our vocal cords. I can tighten the slope tuning on my TS-940 to the point where voice signals are hard to understand, without affecting SSTV reception. So how about giving these folks a little slack, OK?

Well, I guess I've griped enough for one session. Next month, something positive, I promise!

*Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check **Special Events File Area #11** on our BBS (603-924-9343). For listings that were too late to get into publication.*

MAY 1

GLEN ELLEN, CA The Valley of the Moon ARC (WB6DWY) will hold its semi-annual Hamfest at the Sonoma Developmental Center, 15000 Arnold Dr., at McDougal Cottage, next to the fire station. Swapmeet, VE Exams, Ham and Egg Breakfast, SE Station, and more. Talk-In on 147.47 simplex and the 145.35 (-600) Rptr. For info call *Darrel WD6BOR, (707) 996-4494.*

MAY 2

SOUTH BEND, IN A Hamfest Swap & Shop will be held in PARKING GARAGE Downtown on U.S. 33 ONEWAY North by the Society Bank Bldg. and Century Center, across the street from Winter Hamfest. Talk-in on 52-52, 99-39, 69-09, 34-94, 145, 29. Contact **Wayne Werts K9IXU**, 1889 Riverside Dr., South Bend IN 46616. Tel. (219) 233-5307.

MAY 3

ROCK SPRINGS, GA WCARS/VEC Exams will be held at Walker County (GA) Civic Center, US 27 Hwy., beginning at 7 PM. Pre-register with *Alan Painter* WA4QCH, (404) 866-1200, or *Dale Har-*

wood N4VFF. (404) 937-5680.

MAY 8

MANITOWOC, WI The MancoRAD RC will hold its annual Hamfest beginning at 8 AM at the Manitowoc County Expo Ctr., intersection of Hwys. 42-151 and I-43 on Co. Hwy. R. Flea Market. VE Exams. Pre-register with SASE to *MancoRAD RC, P.O. Box 204, Manitowoc WI 54221-0204*. For Info, call *793 (414) 684-9097* days, or *Ron (414) 793-4733* evenings.

MIDDLESBORO, KY Stop in at the Middlesboro City Library for WCARS/VEC Exams at 10 AM. To pre-register, contact *Andrew A. Pitt* WB8WEZ, (606) 248-0046, or *James E. Dyke* KZ8A, (615) 869-4453.

MURFREESBORO, TN The Middle Tenn. DX ARC will sponsor the Murfreesboro TN Hamfest from 8 AM-4 PM, indoors at the Rutherford County Agriculture Center, Old Fort Pkwy. (HWY 96); one mile east of I-24 Exit 78. ARRL sanctioned. Contact *Jerry Sartin KC4ALG, President MTDXARC. Tel. (615) 890-9358.*

MAY 8-9

AMARILLO, TX The Panhandle ARC will sponsor the Golden Spread Hamfest 8

AM-6 PM Sat., and 8 AM-2 PM Sun., at the Amarillo Civic Center, 3rd and Buchanan. Talk-in on 146.67 (-600). Contact *Lettie Hahn*, (806) 358-7115.

MAY 9

ATHENS, OH The Athens County Area will hold its 14th annual Hamfest from 8 AM-3 PM at the City Rec. Center. To register in advance, contact **John Biddle WDBJLM**, 80 Wonder Hills Dr., Athens OH 45701. Tel. (614) 594-8901 after 6 PM. Talk-in on club repeater at 145.15+ MHz. For general info, write to **Carl J. Denbow KA8JXG**, 63 Morris Ave., Athens OH 45701-1939

MAY 14-16

TULSA, OK The 1993 Green Country Hamfest and ARRL Oklahoma Section Convention will be held at the Maxwell Convention Center, W. 7th St., between Denver and Houston Aves. VE Exams. Talk-in on 146.28/.88. Call (918) 272-3081, or write P.O. Box 470132, Tulsa OK 74147-0132, for info. Sponsored by Green Country Hamfest Inc.

MAY 15

AMENIA, NY A Hamfest sponsored by

the Southern Berkshire ARC will be held from 8 AM-2 PM at the Amenia Firehouse on Mechanic St. Talk-in on 147.285+. Contact **WB1CEI**, (203) 364-5266 or **N1GIS**, (203) 364-5976.

CADILLAC, MI The Wexaukee ARC will hold its annual Swap 'N Shop and Eyeball QSO at the Cadillac Middle School starting at 8 AM. Talk-in on 146.98 Rptr. Contact *Wexaukee ARC, P.O. Box 163, Cadillac MI 49601*, or call *Dan Schmidt KE8KU, (616) 775-0998*.

COLORADO SPRINGS, CO A Ham Radio/Computer Swapfest will be held by the Pikes Peak RAS, from 8 AM-4 PM at the City Auditorium, 221 E. Kiowa at the corner of Weber St. Talk-in on 146.971.20. For general info, call **Doug Paris N4TGO**, (719) 495-9346. VE Testing 9 AM-1 PM; call **Rick Brown KD0SU**, (719) 531-9423 for details. To reserve tables, contact **Dennis Ochs N7OGL**, 850 Santa Fe St., Colorado Springs CO 80903. Tel. (719) 630-0704.

CROSSETT, AR A Hamfest & Crafts show will be held from 8 AM-4 PM at the Nat'l Guard Armory on Bus Route 133, Florida St. Sponsored by the Southeast Arkansas ARC. VE Exams at 10 AM. Talk-

Took 10, 15, 20, and 40 meter HalfSquares on Field Day. They went up in the trees as easy as dinoloes. A low GSRV took care of everything close and the HalfSquares made my QRP a big signal for the long hop east and west. On 10 and 15 I thought I had a conduit. Try a HalfSquare!

DIGITAL FIELD STRENGTH METER

FS 73

"SIGNAL CUBE"™

High Performance, Precision Instrument measures in relative and absolute units

- Relative measurements from 60 Hz to the GHz range and absolute measurements from 1 MHz to 100 MHz (Broad band with no tuning adjustment).
- Adjustable length dipole antenna sets required sensitivity (At high gain settings, ambient R.F. fields from local sources will indicate on the display).
- Dipole antenna eliminates need for a counterpoise. (A single antenna type field strength meter utilizes the person holding the unit as the counterpoise).
- Consistent and repeatable readings can be obtained with the Nye Engineering unit since it is not necessary for the observer to hold or be in close proximity to the meter.
- A heavy duty cast aluminum, gasketed cubical enclosure is used. It does not easily tip over.
- The "SIGNAL CUBE" is factory calibrated to a standard for both absolute and relative measurements.

Let's Concentrate Now

Carole Perry WB2MGP
Media Mentors, Inc.
P.O. Box 131646
Staten Island NY 10313-0006

Of all the skills that get taught in a classroom, concentration and following directions are most often overlooked. Perhaps with the rise of technological advances in information storage and retrieval there is a decline in emphasis on the basic memory and concentration skills. As a teacher of amateur radio in the classroom to 6th, 7th and 8th graders, I am appalled at the lack of ability of many students to focus on a task, concentrate, and to follow directions. I am forever pointing out how much time we waste redoing work that was hastily rushed through without thought.

Fortunately, amateur radio in a classroom gives the instructor ample opportunity to train youngsters (and adults as well) to improve their auditory and concentration skills. The very first time I hand out code prac-

tice oscillators to a class is when the first lesson of "listening" occurs. In an average class of 40 youngsters, the children will get 20 keys to practice on, using the "buddy system." They are literally forced to listen to just the person sitting next to them, and to block out everyone else's tones. I smile to myself as they inevitably get very frustrated and try to convince me that it's impossible to hear only their neighbor with so much other "noise" going on all around them. I keep reassuring them that with total concentration they will definitely be able to hear each other.

Of course, as their auditory and concentration skills improve during the term, most of the children become quite good at being able to distinguish particular tones. I remind them periodically about how far they've come. It's a great motivation to do better when someone realizes that with appropriate effort they can master new skills.

By the end of the term, almost every student has improved his or her ability to concentrate solely on their

neighbor's messages, to the exclusion of the other children's sounds and the distractions coming from the hallway outside our room. This exercise is just one example of the "hidden" benefits the children get in a ham radio class. It doesn't matter that every student won't pass their code test; that's okay. What does matter is that in all of my 12 classes, every child will have gotten more self esteem by acquiring basic tools that are needed to be successful in all their studies.

Following Directions

Before we get to the part of the term where some of the youngsters will be filling out the FCC license application, we have an entire lesson devoted to following directions and carefully reading written instructions. (Another valuable lesson!) Because I always like the more tedious lessons to have a little "zip" to them, I make my point about the importance of following directions and reading everything carefully through a little fun activity. I believe that the lessons the children learn through a need-to-know situation or an amusing demonstration will be well learned and well retained.

The following is the "test" paper that I have waiting on everyone's desk when they enter the room. I don't say anything to them. On the

Photo A. Using Morse code in the classroom can improve auditory and concentration skills.

board is written, "This is a timed test—you have only five minutes. Good luck!"

1. Read everything carefully before doing anything.
2. Smile, then sit back comfortably for the next five minutes.
3. Circle the word "everything" in instruction #1.
4. Brush away an imaginary fly. Blink four times.
5. Sign your name after instruction #1.

Portable Power/Charger Only \$ 79.95*

- Multi Output at 3, 6, 9 or 12VDC
- Charge from AC or 12vdc source
- Automatic shutoff at full charge (12v recharge less than 3 hrs)
- Built-in Voltage - Charge Meter
- Sealed lead acid 6.5 AH battery
- Supplied with 12 VDC cigarette plug and UL listed AC adapter
- Weight: 8 lbs. LWH: 7" x 4" x 8"
- Great power for Field Day, Contests, Mobile, HTs, TV, RV, cellular, camcorder, 12v vehicle/boat starter, and all of your indoor/outdoor portable power needs!

Window Mount BWM-1 Only \$ 13.95*

Get your rubber duck outside with the BWM-1 Window Mount. This handy mount clips over your car's window and lets your antenna get out and above the car roof giving you better range into your local or distant repeater. High quality BNC to BNC connector can be used on your own coax or with optional 6' 50 ohm, Model BC 6-174 Cable, priced at only \$ 10.95* You can buy both the mount and the 6' cable for \$ 23.00* (cable and antenna shown in photo are extra cost options)

* prices do not include CA sales tax or shipping & handling
Add \$2.50 S&H per order • Master Card & Visa welcome

6. Mentally subtract 19 from 26 and extend as many fingers as there are digits in the answer.

7. If 9 is divisible by 3, touch your head while you count silently to 11.

8. Draw a rectangle around the word "doing" in instruction #1.

9. Loudly call out your name when you read this instruction.

10. On the reverse side of this paper add 8,457 and 9,063.

11. Put a circle around your answer for #10.

12. If you think you have followed directions carefully to this point, call out loudly, "I have."

13. Cross your left ankle over your right ankle. Then uncross your ankles and slap your right heel.

14. In a low whisper, count backward from 10 to 1.

15. Punch three holes in the top of this paper with your pencil.

16. If you are the first student to reach this point, call out loudly: "I am the leader in following directions."

17. Grasp your throat with both hands and open your mouth.

18. Underline all even numbers on the left side of this paper.

19. Say clearly: "I am nearly finished. I have followed directions."

20. Now that you have finished reading everything carefully, do only instructions #1 and #2.

Not only is this a terrific lesson

that children can have fun with and learn an invaluable lesson from, but it can be a great ice-breaker in an adult

radio class as well. Whether you're a classroom teacher or an evening instructor, remember that we all learn

better in a relaxed, non-threatening environment where it's okay to have fun while learning.

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Space restrictions for the March 1993 "QRP" column did not allow me to include the schematic for the controller. We'll take a look at the entire project this month.

Three of the four chips used in the controller are LM324 op amps. They're easy to come by and very inexpensive. Each LM324 consists of four op amps. The LM324 operates on a single power supply, a great advantage over the 741 op amp. If you build the circuit on pert board, notice the unusual location of the VCC pin (pin #4) and ground (pin #11) of this chip. Also, don't short the output of any of the amplifiers or you may damage the chip.

In the March column I described the array detect and power supply systems, as well as the state-of-charge reference source. This time around, we'll look at the FET driver and the driver switching. A quick look at the over-temperature comparator will wind up the tour.

From the voltage divider the battery sense is buffered by U1C. The output is then run to U1B where it is compared to the SOC reference voltage. Two 22 μ F

capacitors connected back-to-back slowly charge and discharge, depending on the input from the battery sense line. The output, on pin #8, will slowly rise and fall along with the battery's terminal voltage. The output of this amplifier, pin #8, is then routed to two more locations. First, it goes to U3B. This amplifier and U3D compare U3B's output and also act as LED drivers. Op amp U3 controls the function of the charging and charged LEDs.

The output of U1C also goes to U2D. Op amp U2D takes the output from U1C and the SOC reference voltage and will generate a string of pulses when the two voltages are alike. If either one of them changes, the output of U2D will also change. This is how the FETs are switched on and off—by the action of U2D.

The last op amp before the gate driver is U3C. This op amp acts like a switch to provide a nice square wave to the voltage pump. When its output is low, the voltage pump is turned on. This then turns on the FETs and they conduct, passing current from the array to the battery bank.

The voltage pump is nearly identical to the one that I mentioned in the first

part of this series. A 4001 CMOS chip will be used as an oscillator running about 300 kHz. The oscillator runs all the time and is never turned off. Gates C and D act as switches to couple the oscillator's energy into the voltage multiplier diodes. The output runs about +22 volts to the gates of the FETs. This is a bit over the maximum limit of the gates and therefore a 20-volt zener diode clamps the gate drive at +20 volts. This +20 volts turns on the FETs.

Although the FETs have a very low RDS (on), they can still generate heat when passing large amounts of current. The blocking diode will generate more heat at higher currents because of the 0.3-volt drop across it. A 10k thermistor monitors the temperature of the heat sink. U2C is a simple comparator checking the thermistor's voltage drop across the other 10k resistor. When the comparator switches states, the output on pin #8 goes high. This high is fed back to the input of the chip, providing a set hysteresis. This will

Photo A. Prototype for the controller.

keep the over-temperature shutdown from oscillating at the over-temperature point. The output also goes to the LED driver. When an over-temperature condition occurs, the "charging" LED will be forced off. Also, the SOC reference on pin #13 of U2D will be forced high, turning off U2D. Pin #8 of U3C then becomes high and turns off the voltage pump. The FETs are then turned off during an over-temperature condition. Everything will stay this way until the

Figure 2. PC board pattern and parts placement for the controller.

Next month I'll have some troubleshooting tips for the project and some modifications as well.

A Versatile NiCd Charger

Simple to build with off-the-shelf parts.

by Ivan T. Lorenzen W4JC

With the ready availability of all kinds of chargers, you may well wonder why anybody would bother to build one. One good reason is that by adding a few things (like a timer, a latching relay, a constant current regulator, and provision for adjusting both the charging and trickle rates) you will have a truly versatile NiCd charger. It will: (1) satisfy a wide range of current requirements; (2) automatically switch over to a trickle rate at the desired time; and (3) charge any number of cells, from one cell to 18 cells, with any mAh rating from 100 mAh to 1500 mAh. And it won't go back to charging again at the end of 24 hours.

There are probably as many philosophies regarding the best way to charge NiCds as there are people who use them. Some argue that constant voltage is best, others say constant current, and still others argue the merits of pulsed DC over filtered steady-state DC. It has also been argued that, in practice, one will work about as well as another, provided that limits are observed to prevent damage to the cell(s). I have used the constant current method for years and have gotten excellent cell longevity. The original 250 mAh pack in my early Tempo S1T handheld lasted for over 12 years and faithfully delivered its full capacity all that time, until it finally died of old age.

The usual practice has been to discharge the pack until the low-battery indicator comes on. On gear that has no low-battery indicator the NiCds are not put on charge until the terminal voltage is down to 1.0 volt per cell. Instead of the commonly used charging rate of 10% of the cell's rated capacity (0.1C), NiCd life can be extended if the charger is set at 0.08C and left on for 18 to 20 hours to achieve approximately 150% of the NiCd mAh rating (1.5C). At the end of the charging period the NiCds are put on a trickle charge set at one-half the charging rate, 0.04C. The NiCds can be left on 0.04C trickle charge continuously until they are to be used, and they will retain full charge until put into service.

The circuit of this charger contains nothing new and is quite simple. See Figure 2. All components are standard, off-the-shelf parts. The parts list includes Radio Shack

Figure 1. W4JC NiCd charger.

catalog numbers for some of the parts that may not be readily available elsewhere. The 100 ohm and 250 ohm potentiometers are available from Digikey (Telephone: 1-800-344-4539). Wiring is point-to-point, and the parts placement is not critical. Any box of adequate size to hold the parts may be used. The timer is a standard table-top type and sits alongside the charger. The polarized AC female socket supplying AC to the timer and the male polarized AC plug which plugs into the socket on the timer are from an AC extension cord, and polarities must be observed.

When SW1 is closed, AC is applied to the green pilot lamp, the timer clock, and T1. The relay is not yet energized, and its charger contacts connect the regulator output to the trickle adjustment potentiometers, so the desired trickle rate may be set immediately by adjusting R5/R6.

At this point, rotate the timer clock dial until its internal switch closes, sending AC to the "start" switch. Pushing the "start" switch lights the red pilot lamp and energizes the relay. One set of contacts holds the relay in its energized position. The other set of contacts switches the regulator output to the charge position, and the charging rate may be set by adjusting R2/R3. Since the regulator is connected as a constant current device, any number of NiCd cells from one to 18 may be con-

nected to the charger output terminals.

When the timer clock turns its internal switch to "off," both sets of relay contacts open, and the NiCds are switched to trickle charge at the rate previously set. The charge rate will not come on again unless the "start" switch is pushed.

This charger will do what you may now be using two or three chargers to do, and it will do it better.

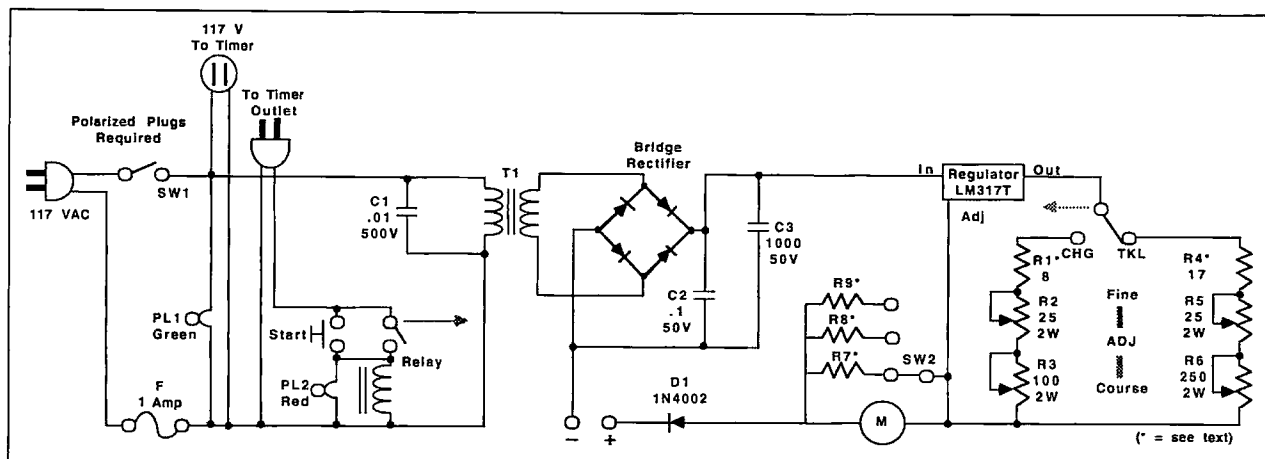

Construction

All parts are mounted on the panel. Remove the panel from the project box or case and temporarily position the parts to assure adequate clearance, before holes are marked and drilled.

The following parts are mounted on a 2" x 4" piece cut from unclad perf board: the relay socket, C2, C3, the bridge rectifier, and the LM317T in its heat sink. If a mounting angle bracket is not available, you can remove the center lug from a tie-point strip and bolt it to the perf board, then mount it on a meter bolt.

A tie-point strip, with one lug cut off, can be mounted on the other meter-mounting bolt and used for the junction of the meter-shunt resistors. A tie-point strip may also be fastened to one of the mounting bolts holding the transformer and used for the several connections in the AC part of the wiring.

The meter-shunt resistors are standard

sizes and will give readings on the meter within the accuracy of the average multi-meter.

A round file can be used to make three notches in the back of the plastic box for the AC cords.

Operating Notes

Always charge cells in series, not parallel, and be sure all cells have the same mAh rating. To put the charger into charge mode, rotate the timer dial until its internal switch clicks ON, then press the "start" switch. The charge rate is adjustable from 10 mA to 150 mA. The trickle rate is adjustable from 5 mA to 75 mA.

If even a short power drop occurs, charging will be stopped. When power returns, the cells will automatically be put on trickle. All you need to do is check that the trickle rate is set at 0.05C (32 mA for 650 mAh cells), and just leave the NiCds on trickle for at least 24 hours or until voltage per cell reaches 1.35 to 1.4 volts, measured with the cell(s) removed from the charger.

To avoid NiCd memory effects, always discharge NiCds down to 1 volt per cell before putting them on charge, and don't take the cells off charge until they have received a full charge.

If you want to check the trickle rate adjustment while the charger is in charge

mode, turn the power switch off momentarily. The red light will go out. Then turn the power switch back ON and adjust the trickle rate as desired. Press the "start" switch to return to charge mode.

Some NiCd battery packs have internal protective circuitry to limit charging current. In this case, the charger cannot be adjusted to force more current than the pack will allow.

Do not over-discharge a NiCd battery pack or you run the risk of polarity reversal in one or more cells. A safe discharge point is considered to be 1 volt per cell. If your equipment has a "Low Bat" indicator, don't try to get more out of it.

PARTS LIST

SW1	AC toggle switch	
SW2	Rotary switch, single-pole three-position, shorting type (make before break)	Radio Shack #275-1385 (All unused switch points are connected together and to the junction of R7, R8, R9 resistors.)
F	Fuse holder with 1 ampere fuse	
PL1	Green pilot lamp assembly, 120 VAC	RS#272-708
PL2	Red pilot lamp assembly, 120 VAC	RS#272-712
START	Momentary push switch, normally open	RS#275-1571
RLY	120 VAC relay, DPDT contacts, with socket	RS#275-217 and 275-220
T1	25.2V, 450 mA transformer	RS#273-1366
C1	0.01 μ F, 500V disc capacitor	
C2	0.1 μ F, 50V disc capacitor	
C3	1000 μ F, 50V electrolytic capacitor	
D1	Diode, 1N4002 or equivalent	
Regulator	LM317T with heat sink	RS#276-1778 and #276-1363
Bridge rect.	100 PIV, 1.5A	RS#276-1152
Meter	0-1 mA movement, marked 0-15	RS#270-1754 (Discard the external 15k resistor)
R1	Two 15 ohm, 1/2W resistors in parallel	
R2, R5	25 ohm, wirewound potentiometers, 2W	#271-265
R3	100 ohm, 2W potentiometer	Digikey #53C1101-ND
R4	Two 33 ohm 1/2W resistors in parallel	
R6	250 ohm, 2W potentiometer	Digikey #53C1251-ND
R7	6 ohms, consisting of one 10 ohm, one 15 ohm and one 220 ohm, each 1/2W, resistors in parallel (Meter scale X1, range: 0-15 mA.)	
R8	1.93 ohms, consisting of five 10 ohm and one 33 ohm, 1/2W resistors in parallel (Meter scale X3, range: 0-45 mA.)	
R9	0.57 ohms, consisting of two 0.47 ohm wirewound resistors in series and then connected across a 1 ohm and a 0.47 ohm resistor in series. (Meter scale X10, range: 0-150 mA.)	
1 pr.	Insulated binding post/banana jacks	
5	Small-diameter knobs for potentiometers and rotary switch	
2	6 ft. extension cords with polarized plugs, cut and connected as shown in diagram	
1	Project box or case of adequate size to accommodate all components—no smaller than RS#270-232 (approx. 8" x 5" x 2-1/2")	
2	Insulated tie-point strips RS#274-688	
1	Prepunched, unclad perf board RS#276-1394	
1	Adaptaplug cord and set of Adaptaplugs from a no-longer-used Radio Shack AC/DC adaptor/charger, such as #273-1652	
1	Pair of solderless banana plugs

ATV Information Sources

The question I am most often asked is, "Where do I find out more about ATV?" Fortunately, there is a variety of publications, newsletters and books dedicated to amateur television. Another good information source is a catalog from one of the ATV manufacturers listed here. Just browsing through one of these catalogs should stir your imagination as you dream about your ideal ATV station.

ATV Publications

There are several publications that cater specifically to the ATV crowd (see the sidebar for address/order info):

ATV Quarterly. This magazine is dedicated to amateur television. It contains a large variety of ATV construction projects, reviews of the latest equipment and an activity news section.

CC-TV. This is the journal of the British Amateur Television Club and offers a wide selection of amateur television projects. Many of the articles deal with FM ATV or video accessories and are fascinating reading.

The Spec-Com Journal. Originally called *A5 Magazine* in the early '80s and before, this publication deals with specialized modes (including ATV). There are also sections about SSTV, packet, weather satellites and OSCAR satellites.

VHF Communications. Published in Europe, this magazine offers a number of VHF and UHF projects. Quite a few ATV articles appear as well. It is available in English (see the sidebar).

ATV Today! This is a newsletter that offers some construction articles as well as a news section showing some of the latest equipment available.

ATV Equipment Manufacturers

There is a wide array of companies

that carry products of particular interest to the ATV community. I've included a list of a number of these, along with a description of the ATV items they carry. You can now purchase a complete ATV station or build your own from the kits and accessories these manufacturers carry.

If you're fortunate enough to attend this year's Dayton Hamvention, you will find a number of these companies represented. There's no better way to decide which route to go than to actually observe the equipment in action at the Hamvention.

ATV Nets

There are two HF nets which meet weekly. If you live in the Midwest or on the East Coast, try listening to 3.871 MHz every Tuesday night at 9 p.m. local time (EDT). On the West Coast, there is a net every Sunday morning at 10 a.m. local time which meets on 7.243 MHz. These nets are an excellent way to meet the area ATVs, ask questions, set up skeds and generally stir up activity.

In addition, there are a number of local ATV nets which usually meet on the 2 meter band. For example, in Southern California there are nets which meet on Monday night at 7 p.m. (Mt. Wilson group) and Tuesday night at 8 p.m. (ATN). Both nets can be found on 146.43 MHz.

Calling Frequencies

The 2 meter band is usually used for establishing contact for an ATV QSO. Some groups use simplex, others use the local repeater. There are, however, a few frequencies that are commonly used for a specific region.

If you live in Southern California, try giving a call on 146.43 MHz; for the Midwest and portions of the East Coast, try 144.34 MHz (parts of Ohio use 147.45 MHz in addition to 144.34).

I hope this helps you to find other ATV activity. It only takes one other station to get things rolling!

HIGH POWER RF SWITCHED PREAMPS

Model 146
\$184
Model 146OS
\$184
Model 440
\$196

Model 146 160W 2 Meters 19db Gain .75db NF
Model 146OS 160W 2 Meters 19db Gain .75db NF
Model 440 70cm 100W 16db Gain .75db NF

All preamps have helical filters to prevent out of band intermodulation in the receiver. Model 146 covers the entire 2 meter band. Model 146OS is of very narrow bandwidth and would be suitable for SSB, Packet, or Satellite. Model 440 is factory tunable from 430-440 MHz or 440-450 MHz per customer request. All models are powered with 13 to 20 VDC and are mounted at the antenna.

Wideband Test Amp and Antenna

This month I thought you would be interested in a simple project that can have multiple uses, namely the ability to observe wide ranges of frequency above 1 GHz with high gain and a low noise figure. Normally, wideband devices like a receiver or a test instrument such as a spectrum analyzer would be used, but they lack the proper sensitivity. The spectrum analyzer that I have is very good but it is 20-some years old and suffers from this same problem. It does have a large dynamic range of 80 to 90 dB, making it very useful. The problem is that its age and related noise figure must be in the 12-to-14 or greater dB range. A small improvement here would make a very big difference overall.

The problem is the same with most broadband receivers. The ICOM R-7000 is an excellent one. It is a super monitor receiver but you have to pay for all its well-thought-out options and excellent sensitivity. I would like to own one but until that day I will be putting things together (like this month's project) to compensate.

Try Surplus

This month's column assumes that you have some sort of broadband receiver or test set that is in need of a high gain, low noise preamplifier. Additionally, with this preamp an antenna is needed to cover the very large frequency band of operation to form the final part of the system. Let's start our

construction of a suitable amplifier by hunting in the surplus market to see if we need to construct from scratch or if we can put to use something that has already been built.

Building from scratch usually poses problems in acquiring component parts. In this case, there is a simple solution: Look in the surplus market for something that exists in quantity. This project, the preamp, is constructed out of a surplus satellite LNA (low noise amplifier). Normally, this amp is built for operation in the 3.7 GHz to 4.2 GHz range, with 30 to 40 dB gain and a low noise figure (something near 1 to 2 dB) for most surplus units I have observed.

Surplus availability is quite good—most people are upgrading their existing systems to lower noise figure amplifiers and smaller dishes. This relegates the older (higher noise figure) amps into the surplus market. The price on the surplus swap meet market is around \$5 as is, \$10 for stated "good" units. Of the several LNA amplifiers of various designs that have passed through my hands, only one had a blown front end stage. All the other LNA amplifiers worked. The defective one showed signs of corrosion and water leakage into the inside of the case. Let's hope you have the same luck with the LNAs that you find.

The application I have in mind for the LNA is not just to monitor the 3.7 to 4.2 GHz band. With a small modification, Kerry N6IZW was able to increase the frequency range of the amplifier to cover from 800 MHz to about 4.2 GHz, with associated gain in the 20 to 30 dB area over bandwidth. There were gain peaks and dips, but for the most part the gain curves looked good.

Photo A. Standard 3.7 to 4.2 GHz LNA.

Construction

The modification is somewhat delicate, but if you're careful it can be done easily. First, open up the LNA by removing the small screws which hold the amplifier cover onto the main aluminum cast body. Remove the cover and the PC board for the amplifier. Now the associated circuitry should be exposed. Looking at the amplifier RF circuits you can see several stubs on the input and output of each stage in the LNA. These stubs are used in the original design to peak up each stage for the best gain and noise figure in the frequency band of interest, namely 3.7 to 4.2 GHz. Using an X-acto knife, gently cut/disconnect these tuning lines (they are the thick lines) from the main transmission line that runs straight from the input to the output of each device. See Figure 1 for details.

Disconnect all such lines, being careful not to disconnect the narrow RFC lines which supply DC power and bias to the FET devices. Also, be careful to ground the work station to prevent static buildup from damaging the devices in the amplifier. When working with the X-acto knife, use a sharp blade and don't press hard on the soft Teflon PC board while disconnecting the tuning lines. Teflon is quite soft and you will go right through the board material if you're not careful. Use light pressure to cut away part of the connection to DC-isolate them. You don't have to remove the entire line, just disconnect it from the main line.

Removing these tuning stubs alters the frequency response of the amplifier gain curve. It will not be peaked up at its normal range but will now give a much broader and lower frequency range of operation. In the unit that Kerry modified, the device gave usable operation from 800 MHz to over 4 GHz.

Once that part of the operation is complete, the input circuit can be changed as we will not be using a waveguide for this amplifier anymore. The input probe in the waveguide cavity must be removed, and an isolation capacitor needs to be added to the circuit first. Locate the place where this probe is connected on the main PC board trace and cut this trace again

with the X-acto knife. On this spot we are going to place a 10 pF (or so) value coupling capacitor to give DC isolation to the input of the amp. In the unit's original condition this was not necessary because the probe was isolated in the waveguide. We will remove the waveguide and replace it with an SMA connector, which requires DC isolation. After the board has been cut to accept the capacitor (a chip type), stop this part of the procedure and unsolder the probe from the PC board, which is now isolated by the cut in the PC board. Remove the probe from the PC board connection.

Now, with a bandsaw remove the waveguide flange, cutting it flush with the top of the amplifier body. Put a piece of masking tape on the open side of the amplifier to keep metal filings from contaminating the PC board area when the waveguide flange is removed. You will also be able to remove the Teflon insulator that insulated the old RF waveguide probe. It should just pop out with a little pressure. Clean the PC board hole where the removed probe was soldered and in its place put an SMA coaxial connector.

The Teflon insulator on the connector might need a little trimming, but some are exactly the right size to slip in the hole where the old Teflon insulator used to be. The center connector of the SMA connector should be long enough to fit right in the PC board hole you just cleaned.

Mark the SMA connector mounting holes and drill and tap for a couple of mounting screws to hold the SMA connector body securely to ground. Now, on the PC board remove the paper tape from the PC board cover plate area and mount the new coupling capacitor to the SMA connector tip and to the other side of the center line you cut before. This will give you DC isolation to the coax connector.

At this point, check the unit for errors. When you are ready, reapply DC power. If you used standard static protection everything should be OK. Even so, amplifiers in circuits are less susceptible to static than loose components. If you used proper care in making the modification, everything should

Photo B. Modified (cut housing) LNA.

be OK. Remember that different units might give varied results, but for \$5 or so, why not give it a try? You don't have much to lose.

Constructing an Appropriate Antenna

Due to the broad bandwidth of the modified amplifier, we needed to construct a new antenna for bench or even outside applications. The normal antennas we had did not cover such a wide range of frequencies. Our station monitor antenna, which works from 50 MHz to over 1200 MHz, worked well but something was needed for the upper frequency ranges. We decided to construct a simple small-scale version of our low frequency monitor antenna, a disccone for the 1 GHz to 4 GHz range. This antenna worked quite well over our frequency range and it is easy to duplicate.

A miniature replacement of the low frequency disccone turned out to be only 3-1/2" high and less than 3" wide at the base and top hat of the antenna. This antenna is basically a funnel turned upside-down, with the bottom spout of the funnel removed. At this point a top hat or disc is electrically connected to the center of the coax cable. In our case we used 0.141 o.d. 50 ohm hardline, quite common in microwave circuits.

The bottom part of the funnel, or ice cream cone, has the coax cable protruding just 3/32" above the small end of the cone (ground portion of the coax). The portion of the 3/32" is all insulator, separating the funnel cone from the top hat. The center conductor is about 1/4" longer, sticking up above this 3/32" of insulation. Mount the top

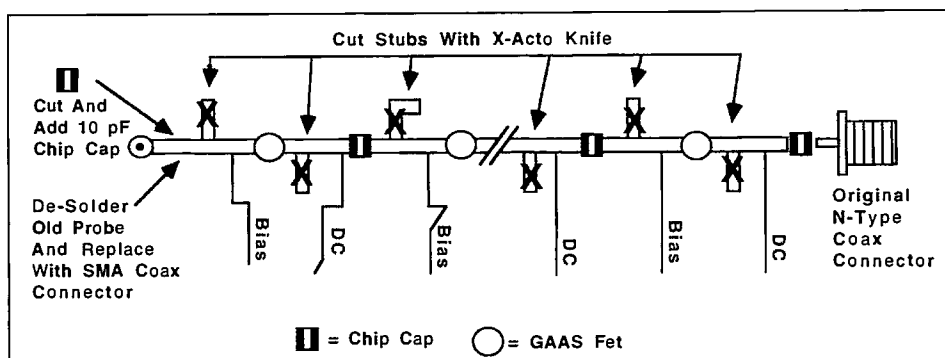

Figure 1. LNA disconnect stubs (example).

hat horizontally to this center conductor, to the top of the cone, and solder it directly to the center of the coax cable. The 3/32" space of insulation serves as an isolator between the top ring and the bottom cone. See Figure 2 for information on the disccone dimensions.

Please note that the dimensions of the disccone antenna are not too critical and there is room for error. Our antenna was cut out of flashing copper about 0.020" thick, and it bends (forms) quite easily. It also solders with small-wattage irons. Most of the 0.141 solid sheath coax comes with Teflon insulation, making it somewhat impervious to heat during construction.

In actual use, the antenna and amplifier functioned well, although no actual measurements were made on antenna parameters. The antenna and amp have been used in spectrum analyzer applications to observe low-level products from workbench construction projects. They can even detect some

of the microwave ovens in the neighborhood. Their operation is on the low 2.2 GHz part of the spectrum. In any case, this conversion should give you increased sensitivity over quite a range of frequency, with lots of gain and a great noise figure, for a little effort and few dollars.

Be sure to keep a good stock of X-acto knives and blades available for conversions on lots of surplus items. After all, who said you can't make a silk purse out of a sow's ear?

Mailbox

The Tin Can filters for 2 meters in the November and December 1992 editions of this column caught Dick N6ISY's eye. He is quite involved with the C.A.R.E.S (Coastal Amateur Radio Emergency Services) group. They use 2 meters for primary communication and have found that when two nets were being run on 2 meters there were desense communication problems.

Their problem is related to the operation of many different types of 2 meter HTs, all operating in close proximity to each other on different frequencies, causing desense to each other.

Since most of today's newer radios are quite compact and capable of operation on wide bands of frequency, this type of problem is common. Some form of frequency limiting is necessary to prevent the excellent front ends from being overloaded or saturated from nearby RF. Quite a few of my HTs suffer in varying degrees from this problem, even from commercial radio and TV frequencies when their transmitters are nearby. The problem is due to the wideband "hypersensitive" front ends that are not tuned to a specific frequency. In this case a filter would help solve the problem.

The cavity or "soup can" cavity can be placed on your antenna lead to provide the required isolation from other frequencies. The narrow passband of the cavity will provide attenuation to the other frequencies, providing the extra margin for operation. We found that the bandwidth of the Tin Can filter was quite narrow, somewhere in the 100 to 200 kHz range on 2 meters (for typical Tin Can cavities). This is dependent on the can size, construction details and coupling link placement. All this can be "jiggled" or adjusted to allow custom design after your first-cut design attempt. There are so many factors involved, however, that most work out well with some re-positioning or different can selection. You just have to try for yourself—all you have to lose is a little time and very few materials.

With small ceramic variable capacitors suitable for low power HTs, running 5 watts would be OK. As always, try out this type of filter with even lower power (100 mW on some HTs) when testing so you don't damage the HT you are using. If pre-tests can be done with something other than a rig, so much the better. I happen to be blessed with a well-stocked workbench, allowing most types of measurements to be made with test instrumentation. It proves to be very valuable to see what exactly is going on. However, lots of small projects can be constructed with a little care and no special test equipment other than an SWR meter.

The Tin Can filter is just a compact

Figure 2. Disccone antenna 800 MHz to 4 GHz.

cavity-high "Q" filler that can be cheaply constructed. It's sort of a poor man's cavity, and it should not cost more than a couple of bucks to construct. All that is needed is two BNC connectors, a tin can, a small ceramic 10 pF capacitor, and a short section of 3/8" to 1/4" hoby brass tube for the center element. Don't worry about the input/output links being a direct short; they are at DC but at 145 MHz they represent something in the order of 50 ohms reactance. At RF this is not a short!

A variation of the cavity is the multi-tuned circuit I covered earlier. There has been some discussion as to coupling loss for different construction types. In the case of high loss, the problem lies in poor circuit-to-circuit coupling between coils. One cure is to place a coupling link in place from one circuit to the other. This is nothing more than a short piece of large diameter insulated wire soldered to the variable capacitor on one circuit and bent near the other circuit. Try several places for positioning; test to improve coupling loss. It's a cut-and-try proposition at best but will make a difference.

As always, I will answer questions on this and related projects. For a prompt reply please send an S.A.S.E.

10 GHz EME Activity

On January 31, 1993, at 22:30, G3WDG and G4KGC made two EME

QSOs on 10 GHz. This is believed to be the first made on this band from the UK. The initial QSO was with WA7CJO in Phoenix, Arizona, at 22:30. This was the second attempt. The first test on January 30 was partially successful as WA7CJO was heard at good signal strength but they could not find G3WDG's signal. This difficulty was caused by a problem in a preamp at WA7CJO's location.

The antenna in use in the UK was a 10-foot solid dish (Andrew 11 GHz version) mounted on an EL/AZ mount originally intended for satellite TV use but modified for a motor drive. The dish was scraped off from a local electronics company where G3WDG used to work. The rest of the equipment consisted of a Hughes 28 watt TWT amplifier. Many thanks to WA5VJB and KY7B for their help in acquiring this tube and refurbishing the power supply.

This is typical of some of the contacts that, with dedication and planning, can be made. I will have more detailed information about this contact and others in my next column. Congratulations for a great job done.

Update

The West Coast VHF-UHF Conference in Ventura, California, is May 21-23, not May 12-14th as originally reported and the ARRL book is \$10 at the conference, \$12 afterwards.

RANDOM OUTPUT

Continued from page 88

intelligence. (Personal note to Mike Galego KA4MUJ: The word frequency is pronounced "free-kwen-see," not "free-ken-see." There's a "w" sound in there.)

Other than giving yours truly the chance to poke fun at these misfits, what does all of this mean? It means that the FCC is finally doing what the amateur radio community has been asking them to do for years: Clean up the mess on our bands. The rest of us are sick and tired of having our frequencies overrun by vermin. We do not care which side of the issue they are on. We want the outlaws rounded up. In fact, it doesn't have to take that long or cost that much money. If the FCC made a concerted effort, dedicating their monitoring stations to policing the ham bands for four random weeks out of the year, I bet our bands would be a lot less messy and the FCC would collect a lot more money. Once they round up all the ne'er-do-wells on 20 meters, they could spend a few nights monitoring 80 meters.

The other thing that needs to happen is we must come up with a way that repeat offenders like Dick Whiten can have their licenses yanked for good. It would be very easy to write something into Part 97 like "the FCC shall have the au-

thority to revoke the license of any amateur radio operator upon receipt of that amateur radio operator's third Notice of Apparent Liability, and that person shall no longer be eligible to receive an amateur radio license." This isn't exactly strict "legalese," but you all get the point. An amateur radio license is a privilege, not a right, and those who abuse the privilege should be banned for life. If you don't play by the rules, you can't play. Period. End of story. Maybe I ought to seriously consider writing up a rule like this and asking the FCC to consider it, all formal and legal-like. What do you think? Would you support something like this? If I hear from enough of you, I'll do it.

Notes from FN42

When it rains, it pours! There was much news in the mail for this month! Some of it will have to wait 'til next month.

It's a small world, again! I went to Boston to have lunch with one of my sons last week, and he introduced me to a young lady who was moving into the building he lives in. She was being helped by two Chinese men and one woman. He told me later that she was from Beijing, China, so of course I asked her if she knew anything about Tsinghua University. She said "no" but the other girl she had introduced me to earlier had graduated with a chemical engineering degree from there. I wish I had known that earlier so that I could have found out if she knows Rick Hunter, our Ambassador for China, who is a student there.

One last thing before all the news. It's that time of year again: the semi-annual pilgrimage to HOSS-TRADERS. The location of the best out-of-doors ham flea market in the Northeast, maybe even in the world,

has been moved from its old location in Deerfield, New Hampshire, to the Rochester Fairground in Rochester, New Hampshire. The primary date is Saturday, May 8th, but the gates will open on Friday, May 7th, at noon. VE testing facilities will be available. All proceeds above expenses go to the Shrine Hospital in Boston. The autumn date is October 16. For more information contact K1ROG @ K1ROG. ME USA.NA on packet.

Look for me at Hossstraders. I'll be the one running around looking for bargains, with no money in his pocket, but having a great time! 73, Arnie N1BAC.

Roundup

Europe Downloaded from packet: Hello Clover users. I have just received a message from Fred DK4ZC saying that many EU hams would like to QSO in Clover with USA hams in order to test their setups and just to have somebody to talk to in this new mode. According to Fred, most of them operate and monitor 21.083, 21.084, 14.083, and 14.084 kHz. Let's give them a hand. Ramon KP4GE @ KP4GE.

Montserrat Letter from Stu

Stephens K8SJ: As reported in the January 1993 issue, I was active from Montserrat in the British West Indies from February 5-17, 1993. My QSO totals were 3,071 CW and 2 SSB, over one-third of those on 40 meters. I contacted 81 countries, all continents, but no JAs (I didn't even hear any).

The equipment was an FT-767GX, 100 watts to an Inverted V at 30 feet. A venerable crystal-controlled DX-20, 35 watts, did 30 QSOs when the FT-767GX fan acted up briefly. Semi-casual operating style (negotiated with the XYL and two young harmonics) was about one hour in the morning, one hour in the afternoon, and three hours late at night.

Special apologies to those I worked on February 16-17 QLF style (sending with my left foot). My arm literally blew out on me. I never knew how strenuous operating a key paddle is in the long haul! I had to relearn how to send with a different finger combination to replace the blown neurons in my thumb and arm! Next time, a memory keyer!

QSL to K8SJ, 1992 or 1993 Call-book address: P.O. Box 266, Girard OH 44420. Foreign hams may QSL through the USA/ARRL Bureau, "VP2MFA c/o K8SJ." Non-SASEs will be routed through the Bureaus.

The Montserrat Tourist Board and Montserrat Amateur Radio Society are very interested in encouraging ham ac-

tivity and visitation of the island. We had a wonderful time with the people the beaches, and the mountains o Montserrat, "The Way the Caribbear Used To Be." It is an extraordinarily beautiful, safe, and peaceful place. The cost of a Montserrat vacation is comparable to a Florida resort stay: Travel costs are a bit higher, but living expenses and accommodations can be quite reasonable on the island. Our total expenses for two weeks were the equivalent of a week at Disney World. And VP2M has better pile-ups than W4!

For further information about Montserrat, write to: Montserrat Tourist Board, P.O. Box 7, Plymouth, Montserrat, West Indies; or Montserrat Amateur Radio Society, P.O. Box 448, Plymouth, Montserrat, West Indies. The ARRL, 225 Main St., Newington CT 06111 has reciprocal licensing info and applications. 73, Stu VP2MFA/K8SJ.

Russia Downloaded from amsat.org, forwarded from SED-SNEWS: The Russian solar sail Znamya experiment ended Sunday, February 7th, when the sail entered the atmosphere. Current reports indicate that initial results went well after it was deployed from the Progress TM-15 cargo craft at the MIR space station about 0400 UTC February 4th. The solar sail illuminated several areas in Europe, especially in Toulouse, France. Apparently in that southern

French city, near the Spanish border, the streets were noticeably brighter during the pass, as seen by several town people.

Shortly after it crossed the day/night terminator in Europe, the solar sail was released from the Progress. The sail then lost altitude until it re-entered the atmosphere on the 7th.

Certainly this ranks as one of the more noticed Russian/CIS space experiments in recent years. (Glenn Chapman, Simon Fraser U., glenn@cs.sfu.ca).

Letter from Dmitri A. Soudov: After having gotten familiar with the November '91 issue of 73 (occasionally received from my American pen pal) there appears to be a strong feeling of nostalgia for my former military specialty as I read about more and more things and problems familiar to me. I was a radio operator during my two-year military service, working as a CW communications operator and receiving high-speed air notification information (also in the CW mode). However, after being demobilized in 1988, I didn't have any opportunity to become a licensed civil amateur, first of all because of having no chance to get proper gear in my country. So, I still remain a SW DXer, my main interest being broadcast stations, but not giving up hope to start again that fascinating hobby of radio communication.

At present I am in contact with several US amateurs who are also interested in the DXing of broadcast stations, and who know about the problem of DXing the stations in CIS broadcasting in the Russian language. Many stations don't send QSLs if the report is written in a language other than Russian. So, I'd like to offer a solution to this problem.

If any of the 73 readers would like to send their reception report to a station on the territory of the former Soviet Union, broadcasting in Russian, but don't know the language, then send your report in English to me. I'll make a qualified translation and forward it to the station you need in the CIS. US\$2 or 4 IRCs fee, please. For an additional US\$2 fee I could keep correspondence with the station by myself and then send you the reply translated into English. This price just covers leasing computer time to compile the reports, and the greatly increased postal tariffs in Russia.

Please send your requests to Dmitri A. Soudov, P.O. Box 96, Kazan-80, 420080 Russia.

Ukraine Downloaded from packet from Lisa KD6BLK: Thanks to my new packet pal in Russia I have the following information to share: Vic, UB5WPR, can receive packet messages addressed to UB5WPR @ U5WFLV.UKR.EU. He loves to hear from people, so if you want to explore packet DX send him a message.

The Ukrainian Amateur Radio League (UARL) informs us that since January 1992 the Central Radio Club of Russia (P.O. Box 88, Moscow) has been demanding additional payment

(except postage) for QSL cards addressed to the Ukrainian radio amateurs. Nobody understands why. So, please DO NOT send any QSLs for the Ukraine via P.O. Box 88, Moscow. Use only the UARL QSL Bureau address: P.O. Box 56, Kiev, 252001, Ukraine.

The Second Conference of the UARL was held on January 30-31, 1993, in Kiev at which the following were elected as officers of UARL: President—Nick Gostry UB5UT; 1st VP—Anatoly Kucherenko UT5HP; VP—George Chiljanc UY5XE, and VP—Serge Bunin UB5UN.

Neuger, 286 Chandler St., Duxbury MA 02332, or via packet: WU1B @ NS1N.MA.USA.NA.

Wahroonga NSW 2076

Australia

The details of the long-awaited changes to the licence structure in Australia were announced at the SEANET '93 convention, held in Darwin on August 31, 1992, and was relayed via phone patch to the various WIA Divisions for a live broadcast.

“... the 70 cm frequency allocation for UK Novice licensees has just been expanded to 432.0-440.0 MHz, i.e., it will now include the satellite subband for the first time.”

For any questions please contact the UARL at: P.O. Box 57, Kiev, 25001, Ukraine, or telephone (044) 446-22-39, Fax: (044) 488-39-68, or packet UB5UT @ UT4UX.KIV. UKR.EU.

United Kingdom Downloaded from amsat.org: UK Novices on OSCAR This week's GB2RS News Bulletin reports that the 70 cm frequency allocation for UK Novice licensees has just been expanded to 432.0-440.0 MHz, i.e., it will now include the satellite subband for the first time. UK Novices will thus be able to access any satellite with a 70 cm uplink, including AO-10 and AO-13.

Of course, the Novice power limit of 3 watts output will pose a challenge, but one that can be overcome. With 3W output, forward gain of 17 dBi (typical of a 40-element cross-yagi—20 elements each way) will produce up to 150W eirp, more than enough to access AO-10 or AO-13 if conditions are good.

UK Novices have call signs with 2*0 and 2*1 prefixes and three-letter suffixes, where * is a geographical indicator (E = England, M = Scotland, W = Wales, I = Northern Ireland, D = Isle of Man, etc.). For example, 2E0AAA would be a Novice in England, while 2D1AAB would be located on the Isle of Man. A “0” in the call sign indicates that the holder has passed a code test and enjoys limited HF privileges; “1” is no-code.

Who will be the first UK Novice to make an OSCAR QSO, and who'll be the first to work one? Sorry, 2E0 won't count as a new country. 73, Ray Soifer (71331.1337@CompuServe.COM)

USA/Guatemala Request from Paul Neuger WU1B via packet: My daughter Lisa N1IAR is considering going to Quetzaltenango, Guatemala, to attend the Casa de Espanol Xelaju Spanish School. I know nothing about Guatemala, the school, or how to get a license for Guatemala. I would certainly appreciate any information you can pass one to me. Address: Paul

a no-code Limited Novice licence allowing voice and packet radio on 2m and 70 cm; “Limited” licences (no HF privileges) may use FM (voice) on the 10m band to encourage its use (and presumably to keep the pirates out of it); amateurs holding both Novice and Limited certificates will come under an Intermediate category of licence; Novices will be permitted higher power outputs, to be consistent with commercially available equipment; and various restrictive rules applying to both voice repeaters and packet radio will be relaxed, permitting greater freedom for experimentation, etc.

All In all, it appears that these changes will encourage many more people, especially computer “whizz-kids” to take up amateur radio. I acknowledge the Wireless Institute of Australia (WIA) as the source of this information.

The WIA has had charge of the amateur examinations for over a year now, with a team of more than 400 registered examiners. It does not appear to be the debacle that its opponents had predicted, but as usual, there are some bad apples. It appears that four examiner teams are under investigation by the DoTC for apparent irregularities in the conduct of examinations. Cheers for now. Those with access to Internet can contact me as “dave@esi.COM.AU” or packet “VK2KFU @ VK2RWI.NSW.AUS.OC.”

QSO Tutor®

Study Aid for the Amateur Radio Exams

New - No-Code Tech. Package!!

Mac
IBM

*Consider the rest,
then buy the best!*

- Runs on IBM compatibles or Macintoshes
- Programs are available for Novice, Technician, No-Code Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radiotelephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pools, or study questions automatically selected by the program from your weakest areas.
- Questions current as of October 1992
- Includes full screen graphics, explanations on appropriate questions and, on the IBM version, a pop-up calculator.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or printed with graphics on Epson/IBM or Macintosh printers.
- Public Domain Morse code tutor is included on request at no extra charge.

Also Available:

QSO Computerizer®

The ultimate companion for controlling late model Kenwood rigs.

- Full mouse driven graphical user interface.
- Controls all functions of TS-950, 940, 850, 811, 711, 450, 440 and 140.
- Includes integrated logging, custom scanning, extended memories with annotation, real time S & multi-meters on screen, GMT, layout of band conditions by license class, and much more.
- Available for Macintoshes and IBM compatible (EGA or VGA only).
- Call or write for details

Compiled by Hope Currier

AEA

AEA has introduced its newest multimode data controller, the PK-900. The PK-900 boasts a powerful triple processor system and provides all standard amateur digital modes, dual simultaneous ports, a PACTOR option, a large back-lit LCD display, a 9600 bps G3RUH/K9NG plug-in

option board, a Direct Digital Synthesis AFSK tone generator, six selectable receive modem tone pairs (from 170 Hz to 1000 Hz), packet and AMTOR maildrop, 16 gray shade WEFAX (with optional software) and much more.

The suggested list price is \$549. For a product data sheet and a list of authorized dealers, contact *Advanced Electronic Applications, Inc., P.O. Box C2160/2006 196th St. SW, Lynnwood WA 98036; (800) 432-8873, (206) 774-5554. Or circle Reader Service No. 201.*

TIMEWAVE TECHNOLOGY INC.

The DSP-59 noise filter from Time-wave Technology Inc. reduces and filters noise and interference to improve radio reception, reducing QRM and QRN on speech, RTTY and CW signals. It uses digital signal processing technology to provide optimum filters for five basic functions: random noise reduction, tone noise reduction, high-

pass filtering, low-pass filtering, and bandpass filtering. The five functions are combined to make five switch-selectable modes.

For prices and more information, contact *Timewave Technology Inc., 2401 Pilot Knob Road, St. Paul MN 55120; (612) 452-5939, Fax: (612) 452-4571. Or circle Reader Service No. 204.*

CONNECT SYSTEMS INC.

The new CS-900 from Connect Systems Inc. is the first low cost VOX (voice-activated) simplex phone patch to incorporate powerful standard features such as a half-second Electronic Voice Delay (EVD), a built-in programming keyboard with digital display, a 90-memory speed-dialer, last number redial, call progress tone detection, a user-programmable CW ID, and more. The CS-900 is totally VOX operated and does not use sampling. There are no sampling noises or interruptions—just smooth natural audio. The built-in EVD completely prevents

syllable and word clipping caused by slow switching transceivers. It will interface with virtually any transceiver. The only connections required are to the mike and speaker jacks.

For the price and more information, contact *Connect Systems Inc., 2064 Eastman Ave. #113, Ventura CA 93003; (805) 642-7184, Fax: (805) 642-7271. Or circle Reader Service No. 202.*

CM TECHNOLOGIES

CM Technologies has introduced a new packet radio software program for the Macintosh called *Savant*. Building on their previous success with *Virtuoso*, they have added a number of useful new features that make AX.25 packet operation on the Mac fast, easy and flexible. *Savant* offers a true Macintosh user interface, including scroll bars in session windows; an edit menu with undo, cut, copy and paste commands; and saving and printing of all or part of any session window. It also has a split window interface with both panes re-

sizeable. Animated icons and text fields in the session windows report the status of the connection: number of packets sent and outstanding, signal round-trip time, and number of retries. Multiple simultaneous connections are supported, each having its own window. *Virtuoso* has full-function digipeating capability and the option to assign an "alias" to your callsign.

For the price and more information, contact *CM Technologies, RR1 Box 83A, Kelley IA 50134; (515) 597-2051, CompuServe: 71574,421. Or circle Reader Service No. 203.*

PacTOR / AMTOR Without a TNC

G4BMK's **BMK-MULTY** software, in addition to unequaled AMTOR performance, now does PacTOR with any ordinary RTTY terminal unit such as CP-1, CP-100, TU-170, ST-6, ST-5000, ST-6000, etc., plus we now have an adapter for PK-232. IBM-PC or compatible required.

Detailed literature upon request. Base version with AMTOR, RTTY, CW and Audio Spectrum Analyzer \$95. Base + PacTOR \$145. Extended version also includes HF WEFAX and SSTV reception \$125. Extended + PacTOR \$165. PacTOR alone \$50. PK-232 Adapter \$49. Shipping \$3. VISA/MasterCard accepted.

Amateur callsign required with order.

State 3 1/2 or 5 1/4 inch disk preference.

NEVER SAY DIE

Continued from page 4

really comfortable with the government treating you like a slave and telling you what you have to do.

If The Schools Are So Bad, What Can Be Done?

I've covered my recommendations for a totally new kind of educational system in my book, *Declare War*, so I won't go into the gory details here. Briefly, I recommend school be made non-compulsory; that tests and grades be eliminated; teachers be replaced by team leaders; schools be open year around; ed schools be closed; teacher certification ended; radio, computer and other high-tech clubs be encouraged; and so on. Probably nothing you'd be interested in.

If you do want to learn more about education you can access a list of the books I've read on the subject on the 73 BBS (603-924-9343).

My, How Things Have Changed! And Not for the Better!

Us old-timers have noticed the way "the world has changed." More crime, drugs, riots, poverty, divorce, homelessness, and porno. Family life is less like the Nelsons and more like the Simpsons these days.

You don't suppose there could be any connection between all this and our educational system, do you? Isn't what we're seeing happening exactly what you'd expect from the education John Gatto was forced to provide? And which he got awards for providing?

But, other than sit around and wring our hands, what can we do about it? The educational establishment has our hands tied. Let's say that you're the one parent in a hundred (or thousand) who actually takes a look at the stupid books your kids are using for texts and you get angry enough to want to at least get the kids better books from which to learn. You'll soon find out what you're up against.

The books are selected by the local school board. You talk with them and find they know little about the books. They just use the recommended book list. So why not run for the school board so you can start changing things?

Two years later you've made it. Then you find that getting better books onto the list, even if there are any, is a multi-year project. It seems that the state textbook commission reviews the books for any specific course once every five years. And here you'll find yourself up against a well-healed sales force from the bigger publishers.

You're up against institutionalized mediocrity. The books are lousy. Many teachers are bad. The classrooms and bells are bad. The curriculum stinks. Our educational system doesn't need a patch job, it needs re-inventing. Patching will be fought at every level by the entrenched system . . . teachers, administrators, unions, textbook

publishers, school boards, and a host of government agencies dependent on the status quo.

Is the situation really hopeless? They got us when we were kids and did us in. They're doing the same thing to our children and grandchildren. Is there no way to stop this institutionalized massacre of our kids minds? Not unless you get mad enough to break through the wall of apathy the system has built for you. Not unless you really want something better for your children and your country.

A good educational system can make all the difference. It can end poverty. It's the *only* way to end poverty. Just taking money away from those who worked hard for it and giving it to those who haven't bothered to get an education because the system defeated them isn't a good answer. We've tried that and it hasn't worked.

A good educational system will cost much less than the bloated bureaucracy we have now. It'll prepare our kids to be competitive in the 21st century with the other industrial nations. It'll give them a happier, better quality of life. It'll bring back inventiveness and creativity. It'll greatly reduce crime and drug dependency. It'll end welfare, cut down on teenage suicide, reduce divorces, improve our health, and perhaps even get us interested enough in government so we'll end the corruption in Washington.

None of this is going to happen with the school system we have now. These miseries are artifacts of the system. If people paid a fraction of the attention to fixing our educational system that they do to ball games, we'd be richer, happier, and healthier. Can it happen? You tell me.

Basis & Purpose Circa 1994

The original basis and purpose for the amateur radio service, as set out in 97.1, and enacted by Congress almost 60 years ago, back in 1934, is so totally out of date that it's about time for the Commission to consider rewriting our charter. A lot of water has gone over the bridge since then.

One of the basic reasons for allocating big gobs of the radio spectrum for amateurs was so that in case of war we'd be able to provide a pool of trained Morse code skilled operators, plus technically skilled personnel to maintain communications equipment. These reasons bore splendid fruit when WWII came along and 80% of our licensed amateurs went to war. I was one of the technicians, so I can attest to the validity of this purpose.

Further, the government bought our receivers from us for war use, so we provided an extra benefit. My Hallcrafters SX-24 was sent to Brazil to help provide communications for the government's Rubber Development Corporation, a project to try and grow rubber trees in the Amazon River area to make up for our loss of rubber from Malaysia, after it had been taken over by the Japanese. I wonder whatever happened to that wartime project . . . I've never seen it written up anywhere.

My old SX-24 may still be sitting somewhere in the Amazon rain forest in an abandoned building.

Another stated purpose for our "service" was for us to help pioneer new communications modes and technologies. Plus, we were supposed to provide emergency communications to help build international friendships.

My, how things have changed in only 60 years! The military has as much use for CW today as smoke signals. And modern equipment servicing is done by exchanging modules, not by electronic technicians and test equipment. Military equipment is so specialized today that 99.9% of us would be unable to help fix it. Heck, what percentage of today's hams can fix their own digitally synthesized transceivers? The military have no further use for hams, even if we were young enough to be of interest to them.

We've seen the whole concept of war change. When WWII came along we had a year or so to train people and build equipment. Now we have 100-hour wars. The military don't even need our frequencies any more . . . and they're sure not going to have much use for our ham rigs. None of these things happened during the Korean or Vietnam wars, and we have no prospect of them happening in any future conflicts we can envision. Modern military communications equipment is just too specialized.

If we're going to bring the Basis & Purpose up-to-date we need to rewrite it to fit our 1993 world.

We might start out with 97.1a, stating that the number one purpose of amateur radio is to provide entertainment for a group of largely retired middle-income older white men. A second purpose is to provide entertainment for the mentally deranged, thus keeping them from committing more heinous crimes. Better they enjoy spewing filth on 14.313, jamming traffic and emergency nets, creating pile-ups to the disgust of foreign operators, and venting their spleens over our repeaters, than molesting little girls . . . or young boys, as one of our best known pioneer repeater chaps did. Oh yes, I seem to remember a convention chairman who got caught at this too.

About the only original purpose we're still hanging in there on is emergency communications. But we're being squeezed hard on this by CB, cellular phones and other new technologies. If our emergency systems aren't capable of tying CB, our ham repeaters, cellular phones, police, fire and other emergency services together, we're not going to be needed for long. We need to clean up our act in this respect. Any volunteers to write articles to help our ham clubs get up-to-date in emergency communications?

We're so far behind in technology these days that it's unlikely we'll ever be able to do much pioneering again. We certainly did do a fine job a generation back, with our pioneering of FM, NBFM, RTTY, SSB, SSTV, meteor

scatter and moonbounce communications, and repeaters. Then, 30 years ago, we dropped the ball.

A New Manifesto

My own agenda is to make our priority the attracting of new, young hams to the hobby as a way to help our country generate the high-tech work force which is going to be needed if we're going to maintain a good quality of life. If we can do that we'd be well worth the investment in the spectrum allocated to us.

If we can generate a hundred thousand school radio clubs with an average of 25 members per club, we'll have the work force we need to invent, build, sell and service the technology of the 21st century.

Next, we need to update our emergency communications systems. I'd like to keep that as one of our purposes. But none of this CW traffic net baloney. Any system which can't handle at least 9600 baud won't be of much value. This means we need to get busy developing effective HF packet systems which will give us the throughput we need. We're doing fine on the VHF's, but we still need to be able to get the traffic dependably through QRM, QRN, QSB, and so on. In my past editorials I've shown how we can establish a communication protocol which will enable us to automatically translate our messages into any language in the world and have a throughput of 25,000 words per minute.

I like the concept of building international friendships, but that's completely incompatible with the ARRL DXCC Honor Roll, so one or the other will have to go. Maybe we can get the League to curb some of their endless contests too. These are not international friendship builders.

Please let me know what you suggest in the way of a new Basis and Purpose for 97.1.

Tackling the Deficit

Let's say that you buy a house and find an old painting in the attic. You take it down to a local antique shop and they give you \$100 for it. Wow! Then you read in the paper that the store has sold it for \$7 million. Would you be upset? Remember, you got what you thought was a good price for it.

Well, there's this 1872 law on the books saying Uncle Sam has to sell land for \$2.50 an acre. One parcel of 17,000 acres they sold for \$42,500 was resold a few days later for \$37 million. Did that make Uncle Sam mad enough to change the law? Har de har. Some of the \$2.50 parcels of land are near the gambling casinos in Las Vegas and have appraised values up to \$47 million.

Nearer to our hearts is the Incredible Uncle Sam (and that means us taxpayers, buddy) giveaway of radio frequencies. We're giving away our radio and TV channels for free, even though the users are making billions

Continued on page 82

using them. Ditto cellular telephone channels, and so on. Isn't it about time we started getting a piece of the action back from these humongous industries which are using our property to make money?

If someone set up shop on your front lawn and started selling things, wouldn't you at least expect a cut of the action? When you open a store in a shopping mall you have to agree to pay a percentage of your sales to the mall in exchange for the location. Is there any reason we shouldn't ask the commercial radio and TV users to pay maybe 10% of their revenues for the use of our property? That would add a few billion to the Treasury. The estimate is that we're giving away \$32 billion just for the cellular channels.

Of course, until you get Congress to change, all more revenues will mean is more spending. It won't cut our taxes one nickel. There are tons of ways for Congress to cut spending, but none of them are yet deemed necessary. What most people don't understand is that no one is actually running the government. Congress makes laws and the president handles foreign policy and is commander in chief of the military. But there's no one minding the store, so we see endless bureaucratic waste, with no easy way to curb it.

Waste? How about \$4.9 billion a

year for outside consultants for government bureaus? That's according to the government accounting office. How about \$1.5 billion for Congressional staffs? We could cut \$30 billion if we ended farm subsidies, and that doesn't count how much we'd save on lower food prices, which are now being supported. Then there are failed farm loans, where we've donated about \$10 billion to the farmers. We might want to cut down on the \$22 billion in food stamps too.

I'll be writing about this in more detail in my *Declare War Update* newsletter, which genuine Wayne Green-haters should consider buying, as it will give them plenty more to hate. There are some fascinating recent books which go into the gory details on how Congress is screwing us, but a warning . . . they could possibly make you mad. They could even put a strain on your 12 to 16 years of conditioning in our school system to not cause trouble and to do as you're told. I know I almost got mad. Worse, it almost made me think!

One of the most amusing books on government waste is O'Rourke's *Parliament of Whores*. P.J. shows how Congress could quickly cut \$337 billion off the budget, without even getting to the small, half-billion-dollar, items. Then there's Gross' *Government Racket—Washington Waste*

From A to Z. And if that doesn't hold you, check out Kelly's *Adventures In Porkland — How Washington Wastes Your Money and Why They Won't Stop*. These are just new books on the subject. There's nothing new about egregious waste in Washington. I've got stacks of books going back 10, 20 and 30 years, all describing the waste . . . and nothing has ever come of it . . . or changed.

The probability is high that nothing will change this time, except that the deficit and taxes will continue to rise.

Continuing Unemployment

I see they're extending the unemployment benefits because people aren't finding jobs. I think I know what's wrong. I've talked with some local businessmen and find they're having the same problem I am. They need more people. They're desperate for more people. But the job applicants just aren't what they need.

What's happened in New Hampshire . . . and all around the country . . . is that larger firms have been laying off their high-priced mid-management staffers. These people have been used to making \$50,000 and up a year, but having worked in mid-management, they've little experience or confidence in making decisions. What the smaller businesses need are people who can start at

around \$20,000 and work their way up by generating sales. Someone who's geared to making \$50,000 has the wrong house, car, clothes, outlook, work habits, eats at the wrong restaurants, and so forth. Worse, they're used to that and are not much interested in settling for a \$20,000 lifestyle. So the job market is glutted with over-priced, under-trained people. Meanwhile, small businesses which need more help aren't able to find anybody they can hire. There just aren't many unemployed who can satisfy the needs of small businesses.

I have some great openings here . . . on 73 and *Radio Fun*, and to help start a couple new magazines, but finding people interested in actually working hasn't been easy . . . and we've been interviewing for months.

Ooops, a Typo!

Morris Blechman N9GVA was understandably upset when our data input person managed to let her subconscious alter his letter in the March issue. He ended his letter saying, "Anyway, I am going to send \$ for your ranting and raving." Naturally this got changed to, "There isn't any way I am going to send \$ for your ranting and raving," slightly altering the meaning. Tsk.

- Packet Radio - Portable & Affordable!

Model BP-1
Packet Modem
Made in U.S.A.

- ★ Simple Installation
- ★ No External Power
- ★ Smart Dog™ Timer
- ★ Perfect For Portable
- ★ Assembled & Tested
- ★ VHF, UHF, HF (10M)

Whether you're an experienced packeteer or a newcomer wanting to explore packet for the first time, this is what you've been waiting for! Thanks to a breakthrough in digital signal processing, we have developed a tiny, full-featured, packet modem at an unprecedented low price. The BayPac Model BP-1 transforms your PC-compatible computer into a powerful Packet TNC, capable of supporting sophisticated features like digipeating, file transfers, and remote terminal access. **NOW is the time for YOU to join the PACKET REVOLUTION!**

CAT-1000 Repeater Controller

The CAT-1000 is packed with features normally reserved for controllers costing thousands of dollars more. If you are in the market for a new controller and want to make every dollar count, the CAT-1000 is your only choice.

Features Include:

- ✓ Voice Synthesizer
- ✓ (475) Word Vocabulary
- ✓ (40) Voice Messages
- ✓ Digital Voice Clock
- ✓ Grandfather Clock
- ✓ (64) Control Functions
- ✓ (60) Position Scheduler
- ✓ (2) Voice Identifiers
- ✓ (2) CW Identifiers
- ✓ Full Feature Autopatch
- ✓ (300) User Speed Dials
- ✓ 300 baud Modem
- ✓ DTMF Key Pad Test
- ✓ Two-Tone Paging
- ✓ DVR Controller Ready *
- ✓ (40) Macro Commands
- ✓ (8) Memory Saves
- ✓ (8) Hardware Inputs
- ✓ (10) Courtesy Tones
- ✓ Reverse Autopatch
- ✓ (10) Emergency Speed Dials
- ✓ LITZ Emergency Alert
- ✓ (8) Remote Control Switches
- ✓ Link (Backbone) or Remote Base
- ✓ DTMF Repeater Access
- ✓ RS-232 and TTL Computer Interface
- ✓ TS-440 HF Remote Base Control
- ✓ Programmable Prefix Codes and Timers
- ✓ Link Tuning (40) Preset Frequencies *

* Requires MP-1000 Serial Interface Card \$59.00

Write or Call for an eight page brochure describing the CAT-1000 Controller, including schematics, voice vocabulary word list, control functions, and programming commands.

CAT-1000 Controller Board \$679.00 Wired and Tested

Other Repeater Controllers with Voice synthesizers from \$379.00

Hams In Low Places

It appears that the FCC has finally given up on the notion that the Amateur Radio Service is self-policing, especially when it comes to the odd assortment of human flotsam and jetsam that washes up on 14.313. The FCC has finally answered the cries of the thousands of amateurs who operate legally and courteously, by stepping up their monitoring of the 14.313 cesspool and passing out some nice fat fines. Bravo, FCC! Please, keep up the good work.

When you add in all the other hams who have found themselves on the fuzzy end of the legal lollipop stick, amateur radio is starting to look more like *America's Most Wanted*. We've got illegal VE testing sessions, we've got false distress calls on the high seas, and of course there's always the illegal long distance exploits of everybody's favorite big mouth, Herbie Schoenbohm KV4FZ. It seems that Herbie, who has so far avoided an FCC Notice Of Apparent Liability (though many of us are still hoping), has also avoided any kind of serious penalty for his theft of long distance service. He was originally convicted on three counts, but an appeal got him off two of them. He was sentenced to two months of house arrest (kinda like being grounded, except it's by a judge instead of your parents), and ordered to pay a \$5,000 fine. Herbie has reportedly vowed to appeal the remaining conviction, all the way to the United States Supreme Court. It always amazes me how biowhards and big mouths who get caught with their hands in the cookie jar think they can appeal their little case to the Supreme Court. Herbie should read a book or something, because I can guarantee him that the Supreme Court won't be interested in reviewing his case. Of course, it is mighty difficult to hear and learn something when your mouth is always open.

I have to admit, I am a bit biased when it comes to discussion of Mr. Schoenbohm (watch out, faithful reader, here comes the dreaded "personal anecdote"). Other than my fundamental dislike for ignorance that passes as insight because of sheer volume, I have had a single personal contact with Herbie that left me less than impressed. It was the week we started sending American troops over to Saudi Arabia in Operation Desert Shield, what would eventually become Operation Desert Storm. I was driving home from work and turned on my HF mobile rig. I finished a nice chat with a fellow in Manchester, England, and was tuning up the band, when I came upon KV4FZ's afternoon speech. He and a buddy of his were operating a phoney net. They were being so ludicrous that no one would have mistaken what they were doing for anything other than a joke. I have no problem with jokes. I had a major problem with what Herbie chose as the subject of his joke. He and his buddy were acting like some kind of para-military relief net for the operations in Saudi Arabia. Even if I didn't have two relatives who had been part of the operation (which I did), and no matter how I felt about President Bush's decision to send American troops to that Godforsaken part of the world (I had mixed feelings), I still think that what Her-

bie and his pal were doing was in poor taste.

I sent out my call sign, was recognized, and had a short conversation with KV4FZ. I asked him if he could see how many people wouldn't find his joking about a potentially deadly situation involving American soldiers humorous. Herbie launched into some incoherent diatribe about how we had no business being over there, and how Bush was a dupe of the oil companies, blah, blah blah, yuck, yuck, yuck. I returned and told Herbie that most people didn't care about the political or corporate ramifications of Operation Desert Shield. I told him that it wasn't about Bush, or oil companies, or American-Israeli relations or any other complex matter. Once we had American men and women camped out on the sand of Saudi Arabia, it was a simple question of how many of those young Americans would die before it was all over. I guess this concept was too large to fit Herbie's narrow frame of reference. I don't think he understood what I was trying to say, so I signed off. Herbie and his buddy continued their fun and games.

While Herbie has yet to get caught in the act of pulling illegal amateur radio tricks, others have not been as lucky. William Moskowitz KA3HSZ of Plano, Texas, will soon be cutting a check to Uncle Charlie for \$2,000. Billy-boy is getting off easy, because it's his first offense. The base amount for malicious interference is \$7,000, but the FCC said they'd give Bill a break this first time. Mighty nice of 'em, doncha think?

The FCC wasn't as lenient with big-time offender Richard Whiten WB2OTK of Taylors, South Carolina. Dickie will soon be "contributing" a whopping \$10,500 to the national debt. The FCC stated that they were really socking it to Dick because of "repeated violation of rule 97.01(D)." Actually, I suspect that Whiten got slapped with such a stiff penalty because his defense was so lame. He didn't deny making the transmissions in question, but said that they weren't malicious interference because "if I had truly wanted to willfully and maliciously interfere, I could have done so to such an extent that communications between other amateur radio operators would have been impossible." Is that not priceless? Maybe we should call this the "Big Gun Defense."

Of course, I do have to express a little sympathy for Mr. Whiten, since the guy he was accused of maliciously interfering with was Michael Galego KA4MUJ. Mikey hasn't paid the piper yet, but like his buddy Herb Schoenbohm KV4FZ, it's just a matter of time before the FCC catches him doing something. KA4MUJ is perhaps the most frequent call sign heard on 14.313. Not only is he on the air himself at all hours of the day and night, but others make tapes of his inane ramblings and play them back over 14.313 when he's not around. When he is understandable (his words are so often slurred that it is difficult to understand what he's saying), Mikey can come up with some of the most hateful, ill-informed, anti-Semitic crapola this side of a skinhead convention. He adores Herb Schoenbohm to the point of suspicion, which is reason enough to question his

The following times are given in Co-ordinated Universal Time (UTC), which used to be called Greenwich Mean Time (GMT). When using the band-time-country chart please note that highest possible frequency is used for the path indicated. For the WARC bands, use as follows: for 12 meters, use 10 and 15 data; for 17 meters, use 15 and 20 data; and for 30 meters, use 20 and 30 data. Sometimes a path will open on a band higher or lower than the one indicated, so be sure to check those as well.

The propagation report for May contains some days that are Very Poor or Poor. These are expected to occur on the 4th, 9th and 10th; on the 16th through the 18th; on the 21st through the 22nd; and on the 25th. You will note that there are only 12 Fair or Fair-to-Good days forecast. May will be a month of unsettled ionospheric conditions and an active-to-storm level magnetic field on the days shown as Poor or Very Poor. Also, some intense geophysical effects may be noticed on the days surrounding the 17th of the month. Quite often you will notice that the forecast conditions take place a day or two before or after the forecast date, so always check the WWV broadcasts at 18 minutes after any hour to discover the trend in solar flux, and the Boulder A and K indexes. Remember that the higher the solar flux, and the lower the A and K indexes, the better the propagation will be.

May is also a month for trends from spring propagation (usually quite good) to summer conditions (usually quite poor as compared with spring and fall). The reason for this is the higher-than-usual absorption during the hours after noon, particularly on the lower HF bands. The ionosphere tends to be a poor reflector during those hours. Short skip on the higher HF bands will be quite good on many days as these frequencies are less affected than the lower ones. You may have noticed that the 30, 40, 80 and 160 meter bands are always better during early morn-

ing and late afternoon and evening hours. May always brings increased thunderstorm activity in the Northern Hemisphere, so QRN will be high on many days.

Note, also, that we are now in the last few years of declining sunspot activity when the higher HF bands will suffer the most. Therefore, you will find that working DX is more difficult in general on the bands from 10 through 20 meters. So, as the fanners say, "Make hay while the sun shines," which also applies to our radio activities in the years of declining sunspots.

There will be a partial eclipse of the sun on May 21st and it will cover North America, except for the Southeast, Arctic regions, Greenland, Iceland, Northern Europe (including the northern British Isles) and the northwest portion of the former Soviet Union.

Let me know how these predictions are working out for you. I'd like the feedback. See you next month.

Contract: The mere glancing at this fine print has just made you legally and morally bound to an agreement with the staff and management of 73 to spread the word. Since you like 73 so much, don't you think one or two of your closest ham buddies might enjoy it, too? Go out and get just one other ham to give us a try.

NEVER SAY DIE

Wayne Green W2NSD/1

Another Extra Class Convicted!

Of course it's just coincidence that the hams who have been arrested and convicted of crimes have all been Extra Class. We all know how bad the language on CB can get. Well, two people have been arrested and convicted for the outstanding use of foul language on CB and both were Extra Class hams. Now I see that NS3K has been arrested for transmitting false distress signals on 14.313.

So much for the baloney about Morse code keeping the riffraff out of our hobby. More likely it's keeping out good guys, otherwise we'd be seeing some of our thousands of no-code Techs getting into trouble.

Now, for you knee-jerk liberals, I'm not putting down the code as a fun aspect of the hobby. It only seems to help unbalance a small percentage of us, so it's probably a reasonable trade-off. I believe NS3K might be able to make a good defense if he pleads that the Morse code so scrambled his brain that he was unable to function within accepted limits.

And I'm not saying that all Extra Class hams are crazy. Not all. But I'd sure like to hear from any Extras who think they can round up at least three non-hams who know them and who will attest to their possible sanity. I don't expect much mail.

Did KV4FZ Poison 14.313?

There is strong evidence that 14.313 has been infected with a debilitating virus for which no known cure has yet been discovered. There seems little question but that Herb Schoenbohm KV4FZ is the ham responsible for releasing the virus. He is, by the way, an Extra Class ham. You've probably read about his conviction for phone service theft.

Almost everyone who tunes up on 14.313 seems to come down with the virus. The best bet is to not even listen to the frequency. Perhaps Dick Whiten WB2OTK can get his \$10,500 fine for jamming 14.313 reduced if he pleads temporary insanity caused by Herb's virus.

If the FCC is actually able to collect anything on fines for outstandingly bad operating on 14.313, they may have a

new source of revenue which could significantly help the Treasury balance off some of the pork barrel waste we can't stop our congressmen from passing into law. Sock it to 'em, Charlie.

Wayne Green Falls Again — Totally!

It's almost enough to discourage someone . . . at least someone not afflicted with a Never Say Die complex. No doubt a genetic mishap. I'm talking (well, writing, actually) about my abysmal failure to get you to keep notes when you buy a new piece of ham gear and let me know how it does for you. I want to know about any problems you have; any successes; how much fun it is; and so on.

I happen to know you're buying ham gear. I know you're buying new transceivers, new antennas, stuff for packet, RTTY, and so on. What I don't know is how much trouble you've had getting it going. I don't know what modifications you've cooked up. I don't know how your dealer has done in helping you, or how the manufacturer has been about helping you. I'm not up here in an ivory tower in New Hampshire, so let me know what's going on.

Other than the usual crapola on 14.313, what frustrations have you with the hobby? Look, we don't have a part of the ham exams designed to eliminate the insane, so we're going to have to deal with a level of fruitcakes. As I've explained, our school system guarantees that we'll have a disturbingly high percentage of people who are uncreative, angry, subservient, and prone to religious causes such as environmentalism.

Worse, there's more than enough evidence to convince me that there's a real possibility that the Morse code itself may be contributing significantly to unbalancing those without a tight grip on reality. I wish the ARRL would cooperate with researchers in fields like this, but of course, as a true-blue dedicated CW organization, I can understand their reluctance to let this can of worms be opened.

We don't know how much the code damages us via just hearing it, and how much may be due to the sharp square-wave pulses of high energy RF from our linears. I guess the best approach is just to deny the whole thing and not worry about it, and to heck with the re-

search already done. Scientists are always being proven wrong, right? Just remember a short while back to the nuclear winter, acid rain, ozone depletion, and carbon dioxide panics. Oh yes, and Alar. And weren't we running out of oil pretty soon?

A Ton of Reviews

If you're interested in buying a new piece of ham gear, you sure want to know what you're getting into before you run up your MasterCard account. That means you want to check out a product review. Well, guess which ham rag has the most reviews? And has 'em first? You probably guessed.

In 1992 we ran 33 reviews, and not one of these products was reviewed in *CQ* or *QST* before we published ours. Not one! Heck, we beat *QST* on the AEA FSTV system by 21 months, the Ameritron linear by 10 months, the Command Tech 2m linear by 19 months, and so on. How about the Drake R8? We beat 'em by 16 and 17 months on that one! These are supposed to be new equipment reviews, not old equipment reviews. The other two magazines reviewed only 25 products each in 1992.

If you've got the background and enjoy writing, you can do worse than volunteer to do new product reviews for us. The prestige is awesome; the pay sucks.

I started off asking for you to let me know your reaction to anything new you've bought. This holds even more for kits. I've had a couple grumbles about some kits, but then I've gotten enthusiastic letters from others about the same kits. If you put together a kit please let me know how it does for you. I want to know if it's a good bargain. Does it do what it claims?

In these days when parts for building are almost impossible to find and circuit boards are full of ICs, we're very dependent on kits for our building fun. Having spent many years at the workbench and still having a bunch of my old homemade stuff out in the barn, I want to do all I can to help newcomers to the hobby to find out how much fun it is to build stuff. I'd love to knock together some kits, but every time I start to buy one I get honest with myself. I look at my desk, with a stack of unanswered mail. I look at the homework I need to

do to put out my *Declare War Update* newsletters for the New Hampshire Economic Development Commission and our legislature. Sigh. Plus, I want to get to Dayton for a couple days, and I have talks scheduled with a growing number of chambers of commerce and Rotary Clubs. So, I tell you what, I'll do my Don Quixote bit, railing against the political windmills, and you put the kits together and let me know how they've done for you.

Cellular and Cancer

As a radio expert you're expected to be able to advise people on how serious this cancer business is for people using cellular telephones. I like the statement by a Motorola researcher that he would not use one for more than 30 minutes a day.

Yes, there is a lot more to be learned, but that doesn't mean that there isn't convincing evidence of the connection. The weasel-words are that we don't yet know how this happens. That's the same excuse the tobacco companies' paid scientists are using to say they've not yet seen evidence that convinces them of the tobacco-cancer connection. If I were being paid as much as they are I'd probably have trouble being convinced too.

If you've kept up with Ross Adey (K6UI) and his experiments, you know he's proven a connection between 450 MHz RF and cell growth changes. We're still learning about how cells work and how they communicate. There are both chemical and electric communications, either (or both) of which could be affected by magnetic or radio fields. There could even be other communications systems.

If you watched the PBS program on sharks you know that some species of sharks can track fish by their electric fields . . . and this is in salt water! Now, if this system is built into sharks, which have been around for hundreds of millions of years, we might want to find out more about how this works and see if something similar is at work in our bodies.

One thing that has really upset researchers is the incredibly low field strength of low frequency magnetic fields which can cause cellular changes. These fields are far more destructive than ever imagined.

With RF it may turn out to be more the modulating frequencies which are detected by our cells than any effects from the RF itself. This is why a couple years ago I suggested that we not put HTs to our head when PL tones are being used. Until Ross and the other top researchers in this field prove that RF is harmless, you have little to lose by considering it a potential danger and keeping your head away from RF. Heck, keep your whole body away from it.

I've been joking . . . sort of . . . about how CW operators are crazier than the rest of us. Well, there's some reason to believe that high-powered RF and power line magnetic fields from a CW-keyed rig just might screw up our cells beyond the ability of our system to self-

From the Hamshack

Klaus Spies WB9YBM, Niles IL Wayne, as one who wants to be an entrepreneur, I thought it's about time I came out of the closet to agree with all of those times you tried to motivate everyone in your "Never Say Die" column. You're right: We should get our fannies in gear, do what we enjoy, and make a living at it. You've set the example with your undertakings.

I've never been certain of what to start an entrepreneurship in (problem number one), and (problem number two) after getting laid off from a job of nine and a half years (as an engineering technician for Motorola), I've been banging my head against the wall trying to figure out how to go about putting into practice what you've been talking about all these years.

Have you thought about writing a "How-To" book for entrepreneurs who want to start an entrepreneurship? (Doing an entrepreneurship on a limited budget would be a topic I'd like to learn more about, too!) You can put my name on top of the list of those wanting to buy a copy. I'll also be willing to bet that if you print this in 73's "Letters" column there'll be a bunch of people out there who'll beat your door down for their own copies of this book!

Ron Koyich VS6BD, Hong Kong Way to go, Wayne! Thank you for another excellent editorial, this one in the January 1993 issue, on health and child-rearing. I feel badly about not giving more thought to the subject before I had a child. Hopefully it will benefit the unborn of those parents-to-be who read it. Maybe not, though, when you consider how many young people do things without much consideration of the consequences. I know I did.

It's never too late to change our attitudes, however, and to embark on a journey of learning more about ourselves. Your editorials have no doubt had some influence on me—for that I thank you.

On the subject of health, a book that my wife and I have enjoyed is *Perfect Health* by Dr. Deepak Chopra. It explores mind/body connections.

Bob Brobst WB9UOF, Alexandria IN In case you get the feeling that no one reads your articles, I want to let you know that I enjoy your controversial editorials. I wish your comments on electrical hazards around us had been published earlier as our daughter-in-law recently lost her premature daughter, very likely due to complications from her computer use of eight to 10 hours a day as a sales rep. Keep up the good work in bringing information to us in a method that makes us think and search for more

information on our own, even when many times we don't feel like we have the time to spare.

Bob, I've been warning about magnetic fields for several years now. You must have missed some of my editorials . . . Wayne

William B. Maddock WA0AIZ, Florissant MO Regarding your March "NSD" column: Aha! I can't believe that an intelligent American in 1993 still believes that the Japanese really surprised Roosevelt or that U. S. military intelligence let the country down. I worked as an intercept radio operator and cryptographer and I worked with men who were assigned to the Naval Intelligence Unit at Pearl Harbor. The Intelligence Unit did its job! On December 1, 1941, the entire Imperial Japanese Fleet in the South China Sea changed call signs and codes. Also, in the ensuing week, the biggest Japanese secret regarding the attack was masterfully put together by Naval Intelligence at Pearl Harbor. The secret: One flotilla was to observe strict radio silence—the flotilla which attacked Pearl Harbor. This flotilla complied to the letter. Not a peep or key click out of them.

Our guys out-foxed this plan and within three days a complete call sign matrix was reconstructed from transmissions made by the rest of the fleet. One flotilla was missing. Conclusion: This flotilla was the one sent to attack the U.S. Almost at the same time a spy was caught noting berthing information at Pearl Harbor (which everyone conceded would be the target anyway, if war came). Condensation of the above: One week before the attack, experts in the field of Communications Intelligence saw what they knew, given the situation between Japan and the U.S., i.e. the call sign and code change at the same time could mean only one thing—war, and war in a very short time. WASHINGTON WAS NOTIFIED BY TOP SECRET MESSAGE. Also, every commanding officer in the Pacific was notified. Three days later, confirmation that an entire war-strength flotilla had broken off from the main fleet and had maintained total radio silence. WASHINGTON AND PACIFIC COMMANDERS WERE UPDATED. During this week, with no reply from Washington, General Short, Army Commanding General in Hawaii, made several significant steps to prepare for attack, including relocation of most of the B-17 bombers to other airfields and airstrips in the Hawaiian islands to avoid concentration of these valuable long-range bombers. (Had he not done this, there wouldn't have been enough recon capability to find the ships which bombed Hawaii.) Admiral

Kimmel, the Naval Commander, permitted all the ships to steam right into their berths at Pearl Harbor as they had done for months. They all came into Pearl Harbor every weekend! Kimmel apparently didn't take any action to protect anything. He apparently had no confidence in Naval Intelligence. Both General Short and Admiral Kimmel were relieved immediately and retired from active duty shortly after the war started—and spent their remaining years in disgrace.

Linda KJ5FC and Dan N5UNU, Brenham TX We visited your boat (*USS Drum* in Mobile, Alabama) and read as much as we could of your newsletters. It was hard to read with so many folks coming through. We wish you a great year in '93—lots more good editorials and much more success with *Radio Fun*.

Thanks for the note, Linda and Dan. It was fun writing about our adventures during the war on the Drum, and publishing the stories in the Drum Newsletter. I probably should have made copies available to interested hams, but it just didn't occur to me . . . Wayne

Joseph Lively KJ5FS, Fort Worth TX Wayne, I must take some exception to your negative assessment of the "service" value of ham radio. I know that a large percentage of what one hears on the bands is far from service-oriented, but in this part of the country the SKYWARN nets on 2 meters perform a valuable service. Last weekend I attended a "SKYWARN School" and have just sent in my application to join RACES so that I can participate. I don't know about you, but large hail and tornadoes scare the #&%! out of me, and I like to be able to keep track of that stuff!

I hope you're wrong concerning the deleterious effects of magnetic fields; it seems like it's getting to where everything is bad for one's health. I think a lot of hams use a lot more power than they need to; many of them on 75 meters use 1500 watts to rag-chew when they could go barefoot and communicate just fine. I am in the process of setting up an HF station, and it'll be barefoot by necessity for some time! I hope the high-power guys don't blow me into the weeds. I don't care whether I'm "30 over S9" or not—I just want to be able to get through decently. It seems to me that if fewer people were so power hungry, there would be fewer strong magnetic fields for them to worry about. After all, the FCC regs state that one should use the minimum amount of power necessary.

Erling A. Gruel WB9QJD, Fond du Lac WI I've been a subscriber/reader off and on since the mid '70s when I got my first ham ticket. I got onto 2 meter FM, and thought repeaters were the best thing to happen to ham radio . . . little did I know. In the last several years, I've kept seeing packet radio editorial comments in

your columns, and just couldn't picture myself using a computer to communicate with other hams. Part of the problems was that I didn't really understand computers and the jargon very well . . . and was a bit afraid of it, too!

After one-too-many Wayne packet rantings, I got brave. I thought: Oh well, why not try it? So I assembled a budget computer system that everyone could laugh at (and some did!). For about \$200 I got an old Commodore 128, a couple of 1541 disk drives, a parallel interface (did I say that?), and an Epson 9-dot matrix printer. Then I really did it—for Christmas I had the wife give me an MFJ packet circuit card to fit into the back of the 128. Cheap, yes . . . but it works!

WOW! What a different world in ham radio! Yeah, I made mistakes (still do!), but I found my touch-typing handy here! After 40 or so days on the air, it's a real challenge, it's interesting, and it's FUN!

As a sideline, I learned more about computers than I thought I could, and now I even use the system for other things, like assembling frequency lists for my scanner radio from research into FCC records. Makes nice copy, and I don't have to have a lot of paper lying around . . . the whole thing is stored on disk until I download it to the printer! (Sounds like jargon to me.)

I always say, "You never get a 'bum steer' from Wayne!"

Dave Kaiser AL7HG, Dhahran, Saudi Arabia I have just received the January issue. You asked, why don't some hams get involved in packet? In my case, my interest in ham radio is as a rag-chewer and in getting to talk to a lot of different people in a lot of different places.

I am a sometimes DXer; I collect DX cards when I happen to run across one. I've averaged 10 cards a year since becoming a ham, and I probably got a lot of those during my first several years as a ham, and less since (perhaps due to better band conditions back in the '60s). If I were an avid DXer and interested in obtaining cards with the help of a DX association repeater, I might invest in packet, but I'm not THAT much of a DXer.

I presume many hams work in computer-related fields. I stare at a computer screen all day; I sure don't want to come home and do the same thing as a hobby.

In my opinion, the new law limiting scanner frequencies is TERRIBLE. We have technology available to do a lot of things, and hams have a license that theoretically permits them to use it, and yet it's possible for a self-interested group (cellular interests) to sneak through a law that has long-range effects on everyone. Many third world countries prohibit ham radio transmissions and the sale of ANY scanners. Is that next?

Domino's Pizza Delivery Driver Summons Assistance with Ham Radio

Only two days after receiving his ham radio license, Store 7036 driver Doug Graham KB7RKY used his newly-acquired skill to summon help to the accident scene he had just discovered.

Being the first on the scene, Graham jumped out of his vehicle and immediately investigated the wreckage for injured bodies. Relieved that there were no visible life-threatening injuries, Graham quickly and professionally used his amateur radio to call for help.

After following the standard emergency procedure for ham radio operators—calling "break, break, break"—Graham finally heard back from someone offering assistance.

"I put out a call to any ham radio operator in the Louiston/Clarkston valley for help," said Graham. "And then another ham operator (Betty Drinnon N7IPU) came back. She said, 'KB7RKY, how can I be of assistance?'"

After asking her to call the sheriff's department and Rescue One, Graham then moved his own car out of the roadway and began directing traffic around the accident. *Reprinted from the March 5, 1993 "Pepperoni Press," the newsletter for Domino's Pizza.*

FCC Proposes Ham Band Spectrum Sharing

Three FCC Public Notices were recently issued underscoring the fact that we as amateurs should get used to the idea of sharing spectrum with other services. Actually, most VHF and higher frequency spectrum is shared. The three news items that the FCC released concern the 1.25 meter, 70 cm and 33 cm ham bands.

Until August 1991, the Amateur Service had access to the entire 220 to 225 MHz band on a secondary basis. The FCC separated this shared spectrum into two exclusive segments. The primary reason given was to accommodate new narrowband technology which would not be compatible with amateur operations.

The Land Mobile Service got the 220-222 MHz portion for narrowband business radio. Ham radio was allocated the remaining three megahertz, 222-225 MHz. The biggest loss was at 220.5 to 221.9 MHz, which amateurs used for control links.

The FCC received more than 550 requests in 1991 asking that they review the 220-222 MHz reallocation. In response to these *Petitions for Reconsideration*, the FCC said they thought that in certain areas of the country, some relief was indeed justified. They said the Commission would entertain a request for replacement spectrum and asked the ARRL to make a specific proposal showing how ama-

teur operations could use shared spectrum without causing interference to existing users.

After considerable amateur and professional testing, the ARRL filed a petition with the FCC. They asked for access to 216 to 220 MHz on a shared basis to "... provide accommodation for ... present and future wide-band data intercity links and other point-to-point fixed amateur stations ... displaced from the 220-222 MHz band." The ARRL said it was not possible to relocate displaced data operations at 222-225 MHz due to the existence of extensive 1.25 meter repeater networks.

The 216 to 220 MHz band is primarily allocated in the United States to the Maritime Mobile Service. The *Automated Maritime Telecommunications System* (AMTS) operates 80 channels on this spectrum. To reduce interference, the League agreed that amateur activity at 216 to 220 MHz should be managed. A power level of 50 watts was suggested, as well as specific frequency coordination. On March 5th, the FCC released a bulletin stating that it would adopt a *Notice of Proposed Rule Making* to provide "... a secondary allocation for the Amateur Service in the 219 to 220 MHz band to be used for amateur auxiliary station (point-to-point) packet backbone networks and other amateur point-to-point fixed communications."

The Commission also recommended operating limits and other measures to ensure that these amateur operations do not cause interference to primary operations in and adjacent to the 219-220 MHz band. We will not know the extent of these controls until the exact text of the NPRM is issued.

On March 10th, the FCC proposed to allocate the 449 MHz band for wind profiler radar systems (sensitive pulsed radars that measure wind speed and direction at altitudes between 1,500 and 53,000 feet) and asked the public whether they should be accommodated in the 915 MHz (ISM) band as well. This really was not a surprise since the government has been investigating several VHF and UHF homes for wind profilers for several years now.

The first thing that comes to mind to most of us is that 420 to 450 MHz is allocated to the Amateur Service. Does this mean that the Amateur Service is losing access to more spectrum? The answer is no! We must remember that amateur radio uses the 70 cm ham band on a secondary basis. What it does mean is that we will be gaining another sharing partner.

The primary user of the 420-450 MHz band is Government Radiolocation. Government frequencies are assigned by the NTIA (National Telecommunications and Information Administration) and not the FCC.

The good news is that the impact on the Amateur Service should be minimal. Wind profiler radars are generally located in remote rural locations and not near the 30-mile radius of

most 70 cm repeaters located in population centers. Furthermore, the government has agreed to take whatever steps they can to minimize the impact of wind profilers on existing amateur repeater users, and installation of the wind profiler network is not expected to begin for another five to 10 years. That will allow plenty of time for repeater owners and wind profiler planners to determine what steps need to be taken to minimize interference to one another.

The 33 cm ham band at 902-928 MHz is lightly used by the Amateur Service. Theoretically, FM repeaters are supposed to be operating on the band with inputs at 906-909 MHz, matched with 918-921 outputs. Amateur TV and packet operation also have extensive ham band-planning at 33 cm. For the most part, however, 902-928 MHz is not used by the ham community.

Internationally, the 33 cm band is allocated to the Fixed Service on a primary basis, with Amateur, Mobile and Radiolocation secondary. The pecking order is slightly different in the United States where the primary users are Government Radiolocation and ISM (Industrial, Scientific and Medical) use. ISM bands are often referred to as "junk" bands since they provide a home for almost any device that radiates energy. Even microwave ovens cook on 915 MHz.

On March 11th, the FCC said they would be permanently allocating shared use of 902-928 MHz to Automatic Vehicle Monitoring (AVM) systems (used to locate and track vehicles using non-voice methods, and to relay information to and from vehicles). The FCC proposed to expand the service to encompass location of all objects, animate and inanimate, and to allow licensees to provide service on a private carrier basis to individuals, the federal government and business band users.

The AVM Service will be renamed the *Location and Monitoring Service* (LMS) which the FCC defines as the use of non-voice signaling methods from and to radio units to make known the location of such units.

The FCC suggested that wideband LMS systems be licensed on the 904-912 and 918-926 MHz bands and narrowband LMS systems at 902-904, 912-918 and 926-928 MHz. The Commission believes that wideband systems are capable of operating in a shared environment, but asked if there is a need to provide spectrum exclusively for some period of time.

Sharing our spectrum with other radio services and the U.S. government is covered in the Amateur Service Part 97 rules at section 97.303. Since the Amateur Service is a secondary user of all UHF and higher frequency spectrum, we simply have to accept any interference that might be generated by those services designated as primary and we must not interfere with their operation. *TNX W5YI Report, Vol. 15, Issue #7, April 1, 1993.*

The Ubiquitous Coaxial Connector

by Steve Katz WB2WIK/6

Connectors . . . can't live with 'em, can't live without 'em. Coaxial connectors, especially, are a real bugaboo for many hams faced with the challenge of installing them in a proper, professional manner and trying to keep the weather elements out of them for any length of time.

Fear not! Coaxial connectors are truly easy to install properly—it just takes the right tools and training (like any job). Luckily, the right tools are likely to be in your own toolbox, or at least at the local discount hardware store. Let's start with the most popular connector in amateur use for 1.8 through 220 MHz, the "UHF" type PL-259.

PL-259 "UHF" Connectors

PL-259 "UHF" connectors are so named because way back when they were invented, any frequency above 100 MHz was considered to be Ultra High. These were the frequencies of our earliest radar systems, and little work had ever been done, except by pioneering experimenters, above this frequency range. Since that time, we have redefined our spectrum to divide it up in "decade" (factors of 10) ranges, and UHF is now defined as 300 through 3,000 MHz. ("VHF," the next decade range below, is defined as 30 through 300 MHz; "SHF," the next decade range above, is defined as 3,000 through 30,000 MHz; etc.).

In any case, UHF connectors are badly misnamed because they really don't work at all well in the real UHF spectrum and their use should be confined to the MF (medium frequency), HF (high frequency, or 3-30 MHz) and VHF ranges. The reason PL-259s work so poorly at Ultra High frequencies is that they are not constant-impedance devices and their physical dimensions are such that they can appear as quite an impedance "bump" (or discontinuity) in the UHF range.

This bump can cause attenuation, which of course is normally undesirable, so PL-259s are best used in the frequency ranges where their impedance discontinuity will be of no consequence. (The bump is created by loose mechanical tolerances in the PL-259 connector design, as well as by variations in the dielectric materials used, construction by different manufacturers, and so forth.)

So, now that we know where we should be using UHF connectors—or at least where their inadequacies can be tolerated—let's install one on a cable.

The PL-259 is designed to accommodate coaxial cables measuring 0.405" outside diameter, like RG8A/U, RG213/U, etc. The rear (cable-entry) end of the connector *body* has internal threads which allow the connector to be literally screwed onto the mating cable's jacket, making a secure mechanical connection prior to any soldering operations.

If you have been installing PL-259s *without* screwing the connector body onto the cable jacket, you've been doing it wrong, and the results can be devastating to prolonged performance.

PL-259s can also be modified to accommodate the smaller-diameter cables, like RG58/U (and A/U, C/U, etc.), RG59/U and RG8X (or RG8M) "mini-8" cables. This modification involves using the correct "reducer" size, type UG175/U for RG58 and UG176/U for RG59 or RG8X, which is screwed into the rear end of the connector body as part of the assembly operation, and prior to any soldering. Whether using the larger-size cables (0.405" o.d.) or the smaller-size cables (which are 0.195" or 0.242" respectively), the rear-end internal threads in the connector body are *always* used.

UHF connectors are available in a variety of construction materials and finishes, but the essential dimensions should always be the same. Popular finishes include bright nickel ("Astroplate" from Amphenol, for example), silver plate, and gold flash. Popular dielectric materials include Rexolite, Phenolic and Teflon. Combinations of plating finishes can be found in a single connector. I find the easiest ones to work with are silver-plated (at least the *body* should be silver-plated, if not the connector shell), with Teflon dielectric. The reason for this is that

Photo 1.

the silver-plated body accepts soldering at a lower temperature than nickel-plated connectors will, making the soldering operation a much easier job; and the Teflon dielectric will withstand soldering heat better, and be less hygroscopic (will absorb moisture less easily) than other materials. The silver-plated Teflon-dielectric connectors cost a bit more than other constructions, but I find they're usually worth the small amount extra.

Installation

To do a professional job in the installation of a PL-259, you'll need an X-acto knife or a sharp single-edged razor blade (sold in wallpaper/paint shops for a few cents each in boxes of 24 or so), a sharp pair of scissors, similar to manicuring scissors (available in stainless steel for about \$5), and a heavy-duty soldering iron, usually a "gun," rated at 260 watts or more, like the Weller D550 or equivalent. It doesn't pay to try using a smaller soldering gun because the heat transfer to the connector will take too long and can cause damage to the cable. If you can't heat up the connector body to the solder-melting point (about 230 degrees C for standard 60/40 alloy solder) in just a few seconds, you're taking too long and will be frustrated. You'll also need some rosin-core solder, usually 60/40 (tin/lead ratio) or 63/37 alloy, 0.047" or 0.050" diameter. The most expensive item here is the big soldering gun, which could cost as much as \$50 or so if you don't already own one.

Prepare to work on a *non-metallic* surface because a metal surface will act as a heat sink and draw heat away from the connector so rapidly that soldering will become a difficult task. I do most of my PL-259 soldering on a slab of ceramic (like a large piece of ceramic tile from a bathroom, kitchen or foyer floor—available for free as "scrap" or "sample" from most flooring shops). Ceramic is an excellent material because it will withstand very high temperatures without burning and is a lousy heat sink.

Prepare the cable end for installation of the PL-259 as follows:

(1) Slide the connector "shell" or "nut" over the end of the cable, with its internal threads facing towards the cable end, and push it far enough down the length of cable so that it's out of the way.

(2) Use the razor blade to cut all the way through the cable jacket, braid, and dielectric materials, stopping at the copper center conductor (you can feel it when you hit this obstacle), using vigorous pressure at first to cut through the braid, then lighter pressure as you slice through the dielectric. Don't use so much force that you cut into the center conductor with the blade. If, after you're done, inspection reveals that you *have* cut into the center conductor a bit, cut off and discard this piece of cable and chalk it up to experience, then try again. With a bit of practice it is easy to know how much pressure to use and to stop applying pressure as soon as the blade touches the center conductor. Perform this operation at 5/8" (0.625")

from the end of the cable. Once you've successfully sliced through in one spot, hold the razor blade in a fixed position with one hand and rotate the cable 360 degrees so that it cuts in a similar manner all the way around the cable.

(3) When you're done, pull off the piece you've just sliced through, exposing 5/8" of undamaged center conductor (Photo 1B).

(4) Now use the razor blade to slice through *only* the cable jacket, which will not offer much resistance to penetration at all. Do *not* use enough force to cut into the braid material. Make this cut another 5/8" down the cable, or 1-1/4" from the end of the copper center conductor. Rotate the cable 360 degrees again, this time slicing through only the outer jacket material. When you're done, pull off the jacket material you've just sliced through, exposing 5/8" of nice, undamaged braid material (Photo 1C).

(5) Inspect the exposed cable end to be sure no braid "hairs" protrude beyond the freshly-cut dielectric material, risking short-circuiting to the center conductor. With practice, you'll find there won't be any hairs, especially if you use a new, sharp razor blade. If any braid hairs protrude beyond the dielectric and look like they might short circuit to the center conductor, use the small, sharp scissors to cut them off, one by one.

(6) Now, line up the connector body with the end of the prepared cable so that the center conductor will center itself with the 0.150" diameter center pin of the plug. If your coax has a stranded center conductor, inspect the strands to make sure they are tightly wound together, with no "rogues" sticking out. If any strands *are* sticking out, gently twist them back together by spiraling *in the same direction* as they already were in the fresh coax, making a neat, tight bundle for the center pin.

(7) Next, begin inserting the connector body onto the prepared cable end, twisting the body clockwise as you push gently on it. You'll find that within a very short distance the internal threads in the rear end of the connector body will "grab" the jacket material and bite into it quite well, resisting the rotation. Continue to gently push on the connector, while rotating it clockwise, until the cable is firmly "seated" inside the connector and no further progress can be made. At this point the center conductor should protrude slightly (about 1/8") from the end of the center pin hole (Photo 1D).

(8) Now you're ready to solder! The cable braid should be showing through all four PL-259 body "holes," which are there precisely for soldering. Place the connector down on your soldering surface with one body hole straight up, and place a gentle weight on the cable a few inches away from the connector to hold it in place. A heavy book is a good weight. Don't clamp the cable in a vise or anything that can crimp it too hard. Coax is fragile stuff. Pull the trigger on your soldering gun, and wait a few seconds for the tip to heat up to soldering temperature, which will usually be indicated by a bit

Photo 2.

of smoke coming from the tip. Holding the solder in the other hand, apply the gun's tip to the connector body, right over the soldering hole, and hold it firmly in place for a few seconds to allow the connector to heat up. Now apply a small amount of solder to the joint between the iron's tip and the connector body, and wait a few seconds for it to flow. Once the solder has flowed, move the iron's tip just a small distance (maybe 1/16") out of the way so the connector hole and braid are exposed, and feed the solder right into the hole. Wait another few seconds for the solder to flow into the hole and completely cover the braid and the hole. When the solder has flowed properly it will look bright and shiny, even after you pull the iron away.

(9) Now, rotate the connector 90 degrees and do the same thing in the next solder hole. This one will go much faster because the connector is already very hot. So hot, in fact, that you could burn yourself on it if you're not careful. (Some might want to use heat-insulating gloves for this whole operation to help prevent minor burns.)

The second solder hole should fill up in just two to three seconds. Now, rotate the connector body 90 degrees again and do the same thing in the third solder hole. Again, this should happen very fast because the connector is already at soldering temperature. Then, rotate 90 degrees again, and fill up the last solder hole with solder.

If you're doing it right, the whole soldering operation should take maybe 30 seconds or so. If it's taking longer than this, it's taking too long and one of the following might be occurring:

a.) Your working surface is drawing heat away from the connector—remember, don't do this on a metal surface!

b.) Your soldering gun isn't powerful enough. Try a bigger one—although the 260 watt model should be sufficient.

c.) Your connector body is not silver-plated, but it is plated with other metals that do not "wet" as well as silver. Or, maybe the connector is oxidized, in which case it should be thoroughly cleaned prior to use.

d.) Your solder is weird, and either lacks a rosin core (which is essential to dissolve oxides that form in the soldering process), or is some higher-temperature alloy. Check it out.

e.) You're not applying enough pressure between the soldering iron's tip and the connector body to get good heat transfer.

10) Take a short break to let the connector and cable cool off a bit. To accelerate this process, I often use a brief squirt of "circuit cooler" (available in any electronic parts store). These "coolers in a can" are made of chlorofluorocarbons (if you don't care about the environment) or chlorodifluoromethane (if you do) and release an extremely cold spray (so cold, in fact, that it can damage your skin if exposed directly), so if you choose to use it, be careful. A brief (two-second) squirt of this stuff will bring down the connector temperature very well, and it helps accelerate the process. If you don't want to use the cooling spray, wait a minute or so for the connector to cool down before proceeding. This is mostly to prevent damage to the cable dielectric, which will also be very hot and could deform if the cable and connector are handled prior to a cooldown period.

(11) Now you're ready to solder the center pin. Use the gun again, applying the tip to the junction of the wire conductor protruding from the pin and the pin itself. Apply a small amount of solder, and when it starts to flow, move the iron's tip slightly down the *side* of the pin to draw the solder down into the connector pin. Add just a bit more solder at the tip, and cover the exposed wire conductor and the opening in the end of the connector pin so there are no holes or gaps here. This operation only takes a few seconds to complete because the center pin is a much smaller heat sink than the connector body.

Wait several seconds for the pin to cool off. Use a sharp diagonal cutter to cut off any extra wire conductor protruding beyond the end of the connector pin. Then wipe the whole pin down with solvent (alcohol, trichlor, flux remover or whatever) and a soft cloth to remove any residual soldering flux. Inspect the pin for any excess solder that might have flowed down the outside of the pin. If there is any (with practice, there *won't* be), use a nail file or fine-grit emery cloth to remove the excess solder. (*Don't* use a large file or rasp, or large-grit cloth, or you risk removing all the silver plating from the pin, which will cause it to oxidize much more rapidly, leading to potentially

disastrous results in the field.)

At this point, you're finished, and, if you have used the spray cooler in step #10, the entire installation should have taken less than 90 seconds from beginning to end. If you waited for a "room temperature cooldown" it probably took more like 120 to 150 seconds. Under no circumstances should this operation consume more than 2-1/2 minutes, and with practice it will go faster and you'll still get professional results.

(12) Slide the PL-259 "shell" up the cable to the connector body, and screw it on to the connector body by twisting the shell clockwise onto the body. After a few twists, the shell should fall loose of the threaded area, enabling you to pull it all the way down the connector so the leading edge of the shell is about 0.150" back from being lined up with the end of the connector center pin (Photo 1E). That's it!

Modification for Smaller Cable

All the instructions thus far were for a standard PL259 assembly on to RG213/U or other 0.405" o.d. cables (RG8/U, etc.). A few modifications are required to the instructions if you intend to use the smaller cables which require reducers. Here are the modifications, in order (see Photos 2A, B and C).

Steps (1) through (5) remain the same. The changes for using UG175/U (for RG58-sized cables) or UG176/U (for RG8X cables) reducers begin with step (6).

(6) Slide on the appropriate reducer over the cable, with the large-diameter (big) end towards the balance of the cable and the smaller-diameter end facing towards the cable end you just stripped. The reducer should have a slightly snug fit over the cable jacket to work properly. If it slides on *too* easily (no force required at all), it will be difficult to make the connector assembly weatherproof. A too-loose fit indicates a non-standard reducer (check to be sure it's a real UG175 or UG176 type) or a non-standard (too small) cable diameter. This should *not* happen with mil-spec cables, but can occur with commercial types.

(7) Line up the small end of the reducer with the cut end of the coax jacket material so the reducer is flush with the cable jacket, where the exposed braid begins. Holding the reducer in this position with one hand, fold the braid back gently using your other hand. It will fold back easily. Gently pull it down, little by little, until it's all neatly folded back along the surface of the reducer. If you stripped the cable properly according to step (4), the braid strands should end exactly at the beginning of the threads on the reducer. If the braid strands end much *before* the threaded area of the reducer you didn't strip away enough jacket material in step (4) and you must start again. If the braid strands are so long that they overlap the threaded area of the reducer, they are too long and will interfere with the connector assembly. Trim the braid strands

back neatly using the small, sharp scissors until they all end right about where the reducer threads begin. The objective here is to avoid having the braid strands pinched between the reducer and the connector body.

(8) You will now find that a lot of dielectric material is exposed between the folded-back braid and the beginning of the center conductor. This is normal. The dielectric must be further stripped off the cable, 1/16" maximum from where the reducer starts, leaving at most 1/16" of dielectric material showing when you're finished. This will leave the stripped (exposed) center conductor quite long, but there is no harm in this because the excess will be cut off.

Now, skip to the *original* step (7), as printed earlier in this article, and follow those directions, *except* that instead of screwing the connector body onto the coax jacket, you'll be screwing it onto the reducer. These threads will mate perfectly if the reducer and the connector body are properly aligned and "squared up" with each other. When the reducer is fully threaded into the connector body, it should push tight up against the connector body, leaving no space between the reducer "nut" (large-diameter part of the reducer) and the connector body itself. If there's any space at all here, the reducer is not properly seated in the connector and this will present a problem with regard to completing the assembly, making it work, and making it weatherproof.

Continue with the assembly procedures detailed in the original steps number (8) through (12). If you have followed these directions precisely up to this point, the cable braid should be exposed through all four connector body soldering holes and the soldering and final assembly operations will be the same as for installing a PL259 onto RG213/U.

Final Notes

My directions differ slightly from those shown in the *ARRL Handbook* and other texts written on this subject in that I instruct you to cut braid and dielectric off flush, so they are both the same length (for the RG213/U assembly), rather than leaving some dielectric exposed between the end of the braid and the start of the exposed center conductor. From my 27 or so years of experience installing probably ten thousand of these connectors, my way works better and will result in a more rugged, reliable assembly. There is *no* risk of producing a short circuit in the cable using my method, if it's done properly, so there's no reason at all to leave any dielectric exposed at the end of the braid.

The photographs accompanying this article show how things look as they're going together, and how they should look when you're done. A properly-installed PL259 is so strong that it cannot be pulled off the cable even with a few hundred pounds of tension. When performing the "pull test" on

my cable/connector assemblies (that is, pull on the connector until something breaks!), I can always stretch and break the cable itself before the connector comes off the cable.

When performing step (2) of these instructions, where you use the razor to cut all the way through the jacket, braid and dielectric, but stop short of cutting into the center conductor, you will probably find it takes some practice to determine where to stop cutting and avoid damaging the center conductor. That's fine! Use a scrap piece of cable and make several cuts until you know just how much pressure to apply to get this right. In time, you'll get the "feel" of this, and then in the future it will be a breeze! Razor blades and knives are very sharp and even a small nick can cut a very deep gash in your flesh. You might want to use workman's gloves to help prevent cuts, or at least keep some Peroxide solution and Band-Aids handy to patch yourself up quickly in the event of a mishap (I've only cut myself about a million times doing this.)

So much for PL259s. My next article will detail the installation of higher-frequency connectors, the popular Type "N" and "BNC," which are usable into the SHF spectrum. These are easier, not more difficult, to install than PL259s, because no soldering of the braid is required.

73

ALUMINUM TOWERS

- Self supporting towers up to 144 ft. at 80 mph winds
- Lasts practically forever - weather resistant
- Tapered models & telescoping "crank up"
- Fold-over kits
- Easy to assemble and install.

NEW

DSP From JPS

NEW

The NRF-7

The new NRF-7 is a medium priced DSP product which provides great flexibility in audio processing. Modes available include atmospheric (white) noise reduction through adaptive peaking; spectral multi-tone notch filtering; notch & peak combined; wide (2400 Hz) and narrow (1800 Hz) SSB filters, with and without spectral notch; wide (500 Hz) and narrow (250 Hz) CW filters with selectable center frequency; and a 500 Hz wide

DATA filter centered at 2200 Hz. Since these filters all operate in real time, they can be used for Break-in CW or AMTOR. Note: noise reduction by adaptive filtering reduces noise by dynamically reducing the bandwidth and is not effective against impulse-type noise. **Only the NIR-10 uses spectral subtraction to eliminate impulse noises as well as atmospheric noise, while retaining the full audio bandwidth.**

Only: \$249.95

The NIR-10, the standard in DSP Noise Reduction, still only \$349.95.
For eliminating carriers & other tones, the NF-60, still only \$149.95.

Portable Packet Digipeater for Emergency Service

by John Neeley K6YDW

During the forest fire season, California has many major fires, some raging for several weeks. A call to amateurs for assistance in communications by various local, state and federal agencies is filled by the volunteers. During these disasters, the agencies involved need more portable packet stations and portable digipeaters. Some locations are not accessible directly from the stations at the remote fire camps due to mountainous terrain or other obstacles. The need for highly portable, battery-operated digipeaters is obvious. Packet stations are used to pass logistical messages to and from the camps, along with health and welfare messages from the firefighters.

The August and September 1987 issues of *CTM Magazine* contained a two-part article by Robert Hoover KA6HZF titled "Captain Kirk's Lunch Box," which was about a totally self-contained, battery-operated, solar-charged portable digipeater. Mr. Hoover's article dealt with a complete package housed in a single GI ammo box. It included a Yaesu FT-23 2 meter HT, an MFJ-1270 TNC and a single 14 amp-hour motorcycle battery, along with an external solar panel.

Photo A. The HT/TNC and battery box connected.

I thought this was a great idea, but I didn't have the tiny HT that Mr. Hoover had. I did have an older Kenwood TR-2500 2 meter HT as a spare, and a spare TNC, the MFJ-1270. Since the TR-2500 is much larger than the FT-23, I had to rethink how I could get this all into a compact package. The answer

was to use two boxes: one for the HT/TNC and the other for a dual-battery pack which also included the solar controller circuit board (Photo A). The following article is a guide to building your own unit, no matter

Continued on page 18

Photo B. Inside the HT/TNC box.

Photo C. Inside the battery box. The solar controller board is in the upper right corner.

Figure 1. Radio/TNC box, top view.

Continued from page 16
what kind of HT or TNC you use.

Radio/TNC Box

The GI ammo boxes are the standard type of box found in most army surplus stores or at flea markets. The size of the box is 5-1/2" W x 7-1/4" H x 11-3/4" (Photo B).

How you prepare the mount for the HT or TNC inside the box depends on which brand you use. Most of the older type of HTs are approximately the same physical size so most will fit in the box the way it was done here.

The MFJ-1270 TNC must first be removed from its enclosure so it will fit inside the box. There are four mounting holes in the circuit board. Take a stiff piece of paper, the same size as the board, and mark all four holes. This will be the drilling template for the TNC board mounting holes. Notice that there is a 5 volt regulator on the end of the board. This must be mounted flush to the inside of the box. First, remove all five LED lamps as they are not required for digipeater

service. I did leave the "Power ON" LED, but bent it up into a position that would clear the inside of the box. This gives me an indication that there is power going to the box. Before mounting the TNC board to the box, using 1/2" metal spacers, first scrape away any paint from the area where the 5 volt regulator is going to touch and apply a liberal amount of heat-sink compound. Also, the top two mounting holes will require the use of flat-head type bolts instead of roundhead types. This allows the top lid of the box, which has some long sides, to clear the boltheads.

The mounting of the HT unit will depend on just what you are going to use, but most can be mounted in this fashion. See Figures 1 and 2. I used some scrap 1/4" aluminum plate for both the top and bottom shelves. The bottom shelf is bolted to a piece of 1"

Figure 2. HT mounting scheme.

aluminum angle stock, approximately four inches long, and this angle stock is then bolted to the side of the box. On the outside of the box, where the bottom shelf attaches, is a large heat sink to dissipate any excessive heat generated either by the units inside or by any direct sunlight on the box. There are different ways in which the heat sink can be mounted to the surface of the box, depending on what style of heat sink is used, so I will not go into the details.

In cutting the bottom shelf for the HT, place the HT down on the plate and trace out the outer dimensions. Now, mark the plate 3/8" larger on all sides, as this will give

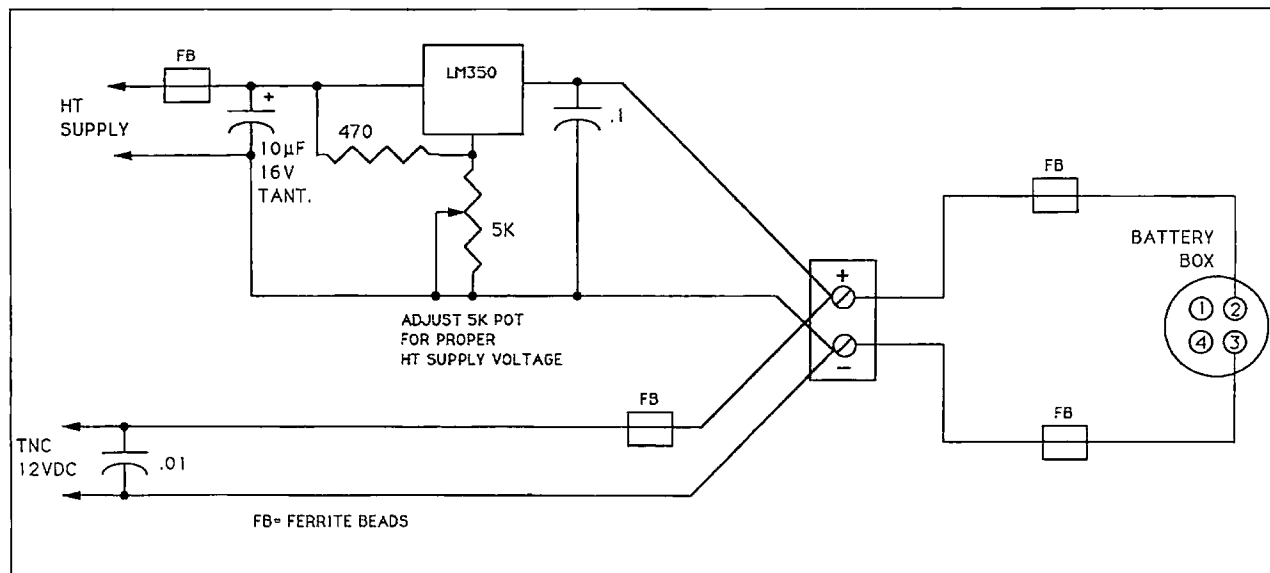

Figure 3. 1.2-32 volt variable power supply.

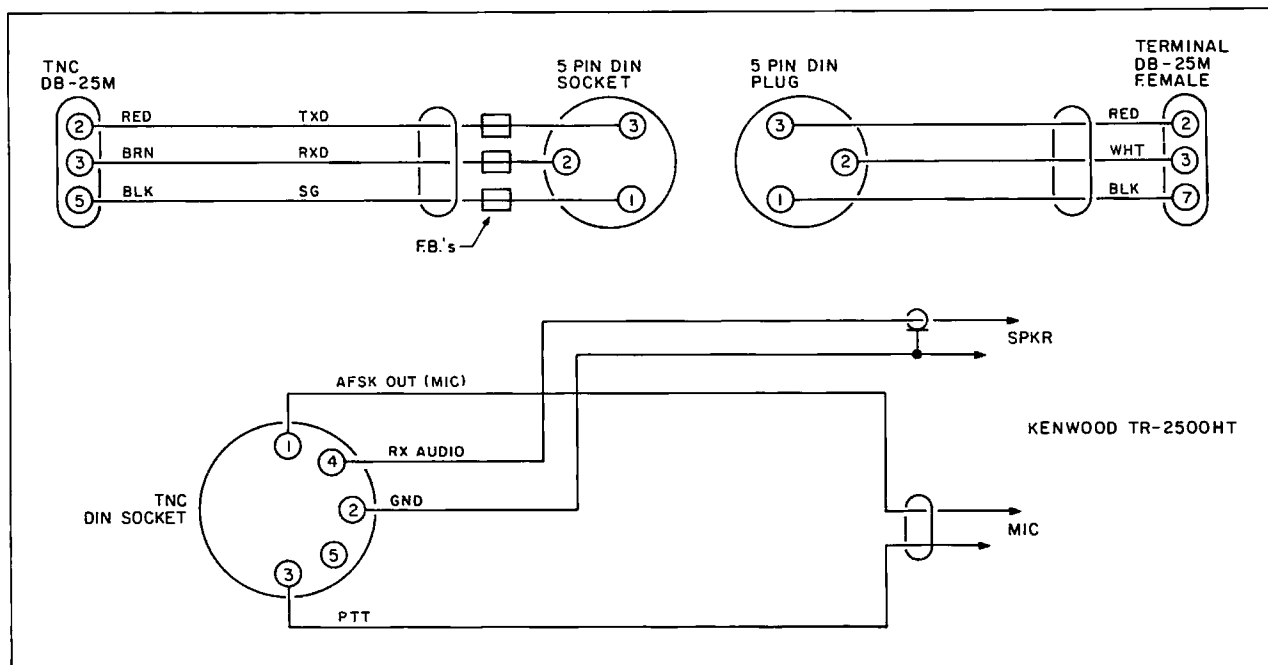

Figure 4. Detail "A."

room to place the mounting bolts. Make the top shelf the same size as the bottom, cutting out for any controls, displays, etc. I used 2-1/2" x 6/32" bolts, using metal spacers to get the correct height needed between the two shelves. Once they are tightened down the HT is very secure.

Three holes are required in the end of the box for the antenna output, the battery input and the RS-232 I/O port.

Since the Kenwood TR-2500 HT uses an LM-340-8K voltage regulator on the outside of the box, next to the large heat sink. Be sure to heat-sink this TO-3 package.

The power voltage required will depend on what HT you plan on using. Some use 12 volts, some less. For voltages other than 12 volts, a simple regulated supply is on the same board as the solar controller and uses a

LM350 regulator. The 5k variable resistor will change the HT supply voltage and can be adjusted for the TH you use (see Figure 3).

Different brands of TNCs are of various physical sizes. Some may mount in the box without having to remove the enclosure. Be sure that the TNC has a "watchdog" circuit to prevent a locked keydown condition. Some TNCs do not have this feature.

Since I planned on using the unit as a portable packet station, I put a 5-pin DIN jack on the outside of the box for my RS-232 I/O port. Placing a DB-25m plug on a 3-conductor ribbon cable, which connects to the DB-25f connector on the TNC, the other end is connected to the 5-pin DIN (see Figure 4). Place a single ferrite bead on each line to the DIN jack. Also, place as many ferrite beads as possible on all lines within

the box. This is just a precaution against any stray RF that may be floating around inside the box. [Note: I have had no problems with stray RF within the box and next to the bare board TNC, even with the plastic case of the TR-2500.]

Battery/Solar Charge Controller Box

I was unable to install a single motorcycle battery inside the same box as the HT and TNC so I had to get a second box. There was plenty of room inside this second box so I decided to use two batteries, which would give me a total of 24 Ah (see Figure 5 and Photo C). Mounting the batteries is fairly simple as they will fit in sideways, leaving approximately four inches on one end for the solar charge controller board and associated output jacks. Be sure to measure the size of the batteries to make sure they will

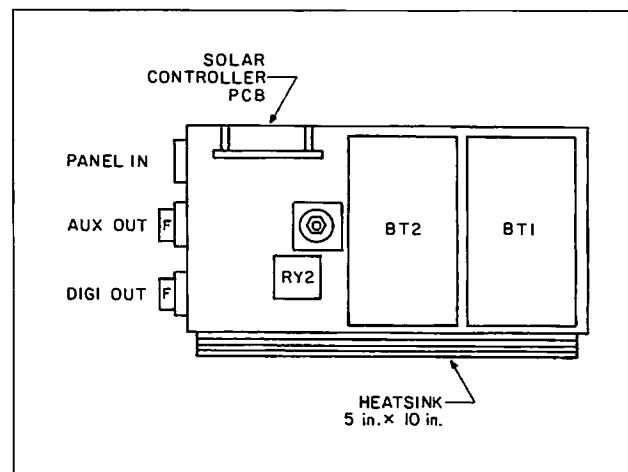

Figure 5. Battery solar controller box, top view.

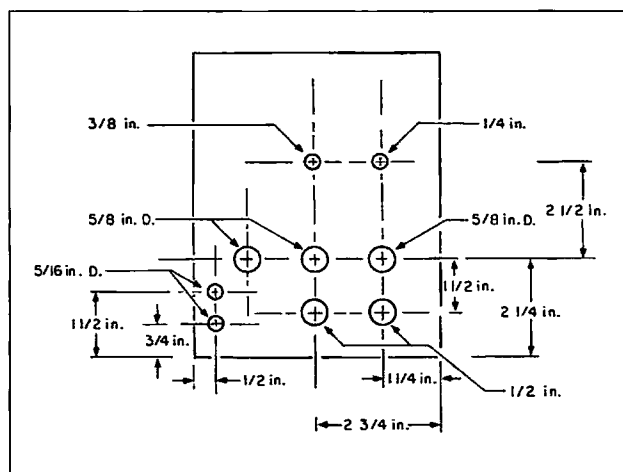

Figure 6. Battery box.

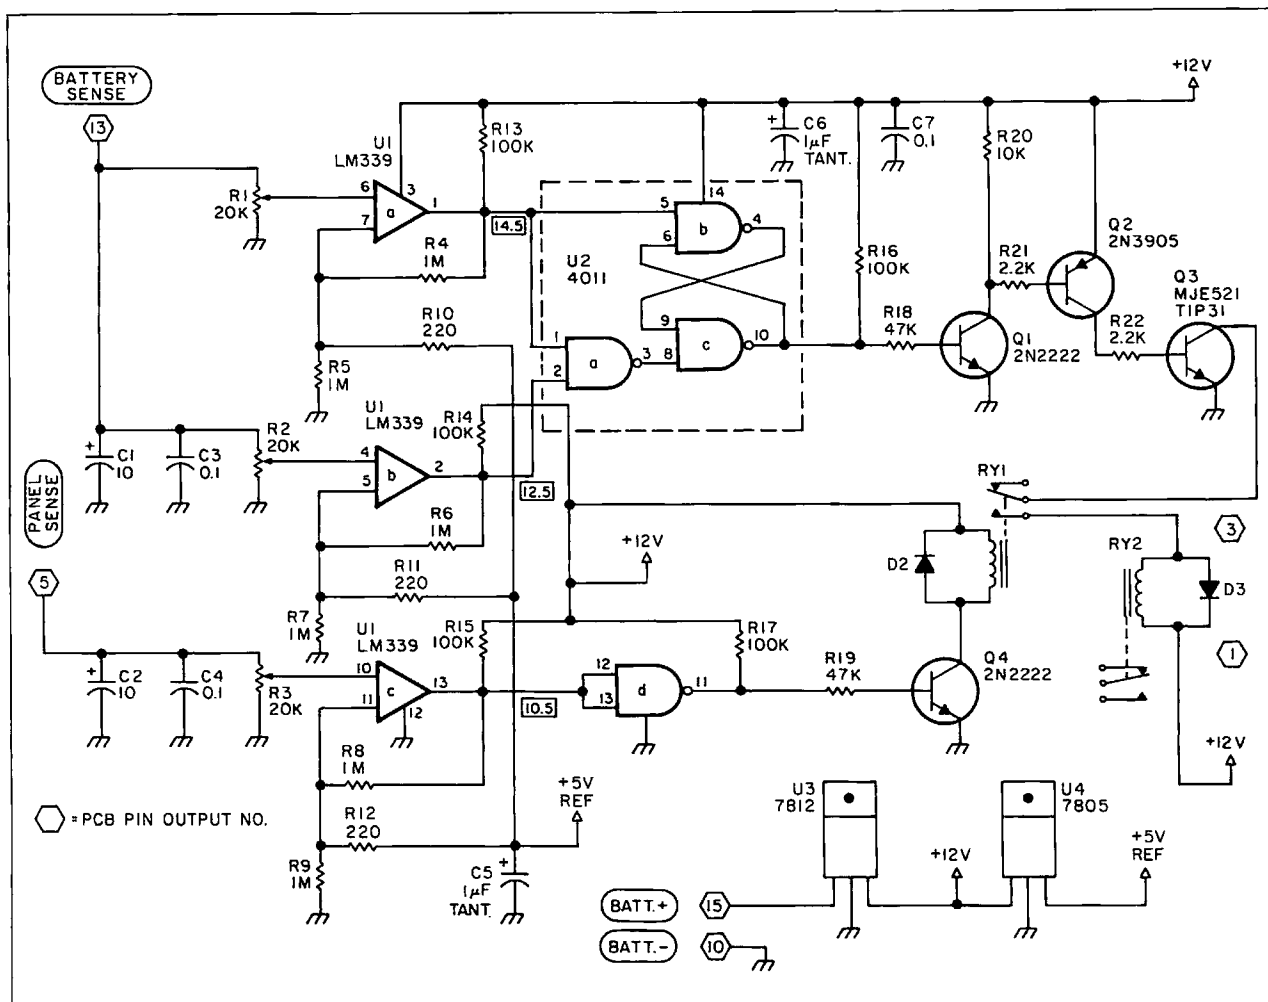

Figure 7. Schematic for the solar controller.

fit inside the box. It is a snug fit, but not binding. Make a metal bracket to hold the batteries in place so they won't shift around. I used a piece of angle steel stock for my bracket.

The output jacks on the outside of the box

are for DIGI, AUX OUT and PANEL IN. The DIGI jack is the power for the RADIO/TNC box and has a one amp fuse inline with its output. The AUX OUT jack is a parallel jack with the DIGI jack, with a 3 amp fuse inline. This AUX OUT jack can be

used to power any external unit, like a transceiver, another digipeater, etc. The PANEL IN jack is the solar panel input to the charge controller. You will see in the template drawing of the box (Figure 6) that I have placed two 5/16" holes near the bottom of the box. These are for the breather tubes coming from the batteries. Also, the "Charge" LED and power switch for the controller are mounted on the end

of the box.

Solar Charge Controller

The basic circuit for the controller uses three sections of an LM-339 voltage comparator IC (see Figure 7). Two sections are used to monitor the HIGH and LOW battery voltage, and the third section is used to monitor the voltage output from the solar panel. I found several articles dealing with solar charging in various publications, and by combining features of these articles I came up with my own simplified version. The project can be built on a printed circuit board available from FAR Circuits, 18N640 Field Court, Dundee IL 60118 for \$8 plus \$1.50 S & H.

Alignment of the circuit will require a variable power supply (+10-15V), a digital VOM and a logic probe. First, connect both the battery sense and panel sense input lines to the same point. Adjust the voltage output of the supply to 14.5 volts and place the logic probe on pin 1 of the 339. Adjust the 20k pot, R1, to where the probe goes LOW. Set the power supply to 10.5 volts and adjust R3 to where pin 13 goes LOW. Rock the supply to make sure all the set voltage points are set

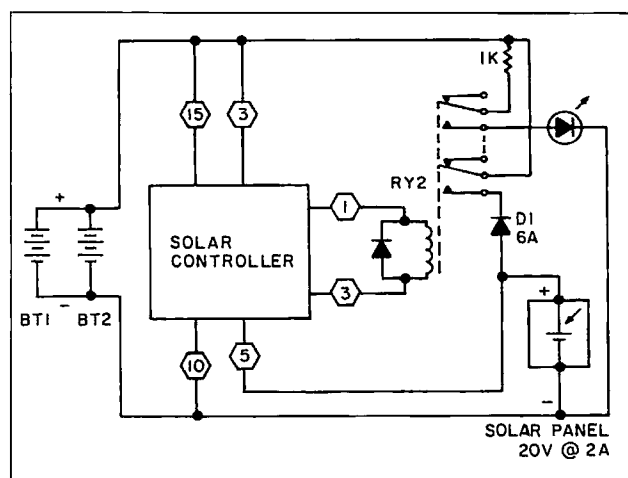

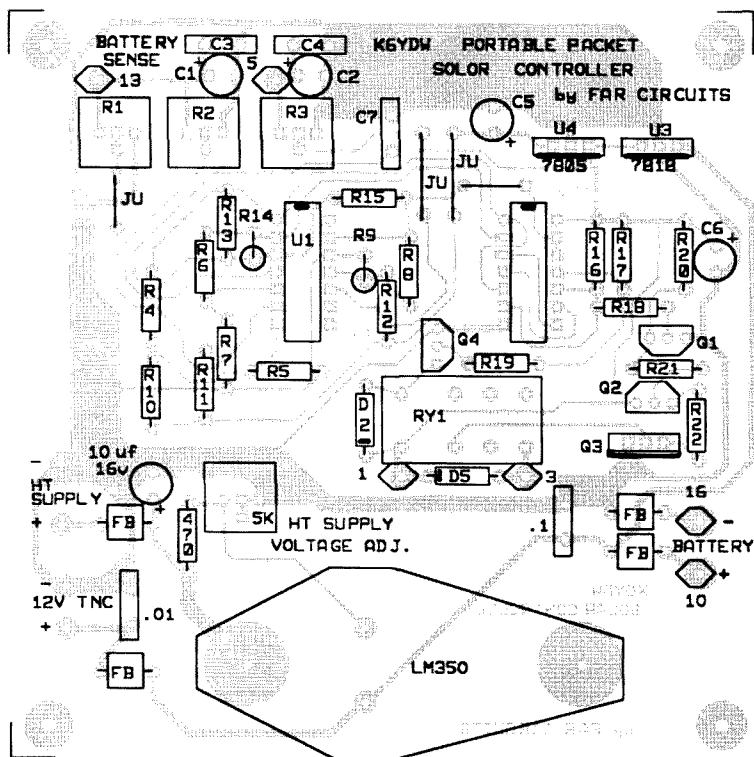

Figure 8. Solar controller external wiring.

correctly. The controller is now ready to be mounted in the box.

Attach the battery sense line to the positive battery post on the battery. Do not attach it to any other point. Then, attach the panel sense line to the output of the solar panel, making sure you have connected it on the anode side of the blocking diode, D1. The blocking diode is used so the panel sense circuit will not be fooled by the voltage output of the batteries. The 10.5 voltage sensor portion of the circuit is not required; it's just as an added feature. The charge circuit will work without it, but I use it as a "day-night" switch. See Figure 8.

Operation of the controller is fairly simple. As long as the panel sense voltage is above 10.5 volts the circuit is active. If the panel sense voltage falls below 10.5 volts, then RY1 is disabled, thereby preventing any charge voltage to the batteries. When the voltage from the solar panel rises to above 10.5 volts, RY1 is connected between the collector of Q3 and the coil of RY2, which allows any charge voltage from the solar panel to flow when requested by the controller circuit.

When the battery post voltage falls to 12.5 volts, pin 2 of the LM339 comparator goes LOW, thereby turning on RY2, allowing current to flow from the panel to the batteries for charging. When the battery post voltage reaches 14.5 volts, pin 1 of the 339 will go LOW, turning off RY2. The "float charge level" is 14.5 volts for most lead-acid batteries.

General Information

The total weight of both boxes is 33 pounds, fully loaded. This weight is a bit excessive, but you have a rugged and, for the most part, weatherproof unit that can be placed in any location desired, like under a large boulder, bush or tree, and it will provide signals to reach from your remote location to the next digipeater.

For an antenna I use a modified Hustler CG-144 5.8 dB mobile whip to which I have attached three radials. This antenna is then mounted on a 5-foot section of TV mast. Three other 5-foot sections are added to give a total height of 20 feet, which can be placed in the rocks or self-supported with some nylon rope. For coax, a good choice is RG-8/x mini-foam, as it is quite flexible and has good characteristics at this frequency. For the two-conductor cable between the two boxes, use a good quality cable which has a heavy outer sheath. I also use this type of cable between the box and the solar panel. For all power connections I use 4-pin micro-processor connectors. This type of connector provides screw mounting, which gives security in remote locations where other types of connectors could be pulled out by animals walking by. For this reason, do not use phono type connectors.

For extra weatherproofing protection, you can cover the boxes with a small tarp. This

Figure 9. PC board and parts placement.

will also shield the boxes from any direct sunlight. Also, turn both boxes to where the heat sinks are facing north, or are in the shade all the time.

The boxes should be painted with a good quality rust inhibitor paint. The bottom and the side on which the large heat sinks are mounted should be a flat black finish. Other areas should have a light-color finish to help reflect heat.

The dual-battery setup will provide plenty of backup power in case of poor voltage output from the solar panel due to clouds, smoke or haze. I have run a test using just the fully charged batteries alone, with no charger in the circuit. When I set the TNC to beacon one line of text every 10 seconds, and the HT to full power of 2.5 watts out, it ran for five days with only a half volt (0.5V) drop through the test period. There is no reason you cannot use just a single battery instead of two. The total package would be lighter by about 15 pounds.

Operation

The system should be set up before you transport it to a remote location. Plug your terminal into the RS-232 I/O port on the HT/TNC box, then apply power to the system by plugging in the power cable from the battery box.

The following parameters are for the TNC-2 type, for unattended digipeater service:

CONOK-OFF: DWAIT=0:
TXDELAY=50: DIGI=ON:
USERS=0: MON=OFF:
HID=ON

Unplug the power cord and disconnect the terminal. You are now ready to use this system when needed.

Whatever HT/TNC and battery combination you use, it will have to be a special design to fit your needs.

Parts List for Solar Controller

Integrated Circuit		
U1	LM339 voltage comparator	RS276-1712
U2	4011 CMOS quad two-input NAND gate	RS276-2411
U3	12 volt voltage regulator	RS276-1771
U4	5 volt voltage regulator	RS276-1770
Transistors		
Q1,Q4	General purpose NPN (2N2222, 2N3904, etc.)	
Q2	General purpose PNP (2N3905, etc.)	
Q3	TIP31 NPN	RS276-2017
Diodes		
D1	Silicone 50V at 6 amps (1N5400, etc.)	
D2,D3	1N4001	
Resistors		
R1,R2,R3	20 kilohm 15-turn trimmers	RS271-340
R4,R5,R6,R7,R8,R9	1 megohm 1/4 watt	
R10,R11,R12	220 ohm, 1/4 watt	
R13,R14,R15,R16,R17	100 kilohm, 1/4 watt	
R18,R19,R22	47 kilohm, 1/4 watt	
R20	10 kilohm, 1/4 watt	
R21	2.2 kilohm, 1/4 watt	
Capacitors		
C1,C2	10 µF, 35V electrolytic	
C3,C4,C7	0.1 µF, 50V disc	
C5,C6	1 µF, 35V electrolytic	
Relays		
RY1	12V DPDT (16-pin DIP)	RS275-249
RY2	12V DPDT (10 amp contacts)	
Batteries		
BT1,BT2	12V at 14 Ah motorcycle-type or gel-cel	

Circuit boards are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118 for \$8 plus \$1.50 S & H.

16 Tips For Using PCB Layout Software

You can do things differently when you design a PCB on your computer.

by Jim Tarchinski N8PTG

Fewer and fewer printed circuit boards (PCBs) are laid out by hand these days. The reason is simple: More and more hams are using computers to create the artwork for their boards.

There are many reasons for this trend away from hand-taped artwork, but there are two main ones. First, prices for PCB layout packages are only a fraction of what they were just a few years ago. In fact, there are even a few shareware programs floating around that allow you to lay out a board on your computer (see the sidebar). Prices are definitely in a range that is affordable to most casual PCB creators.

The second reason layout programs are becoming so popular is that they can shorten the time it takes to design a board from scratch. This is especially true if the software can automatically route the traces, or check your traces against a network connection list (netlist) generated by a schematic drawing program.

Like any other change, however, going from hand-taped to computer-created artwork requires you to change your thinking somewhat. There are some things that can be done, or even should be done, differently. I've learned a few tricks in the year or so that I've been using a layout program, so I'd like to share some of them with you. This article offers 16 tips to help you make

a smooth transition to creating computer-based PCB layouts.

Tip #1

Before you even begin to lay out a board, give some thought to how it will eventually be mounted. If you bought an enclosure at the last swap meet that will work perfectly, you'll need to consider this up-front. This could influence your selection of components or your decision on the layout.

Tip #2

Except for the tip I just mentioned, don't decide on a board size until you make an initial layout and get a rough idea of how much board area is required. Once you have a good handle on this, be sure to select either a standard PCB size or the size of a remnant you have on hand. After all, why cut a larger board down to size if you don't have to?

Tip #3

Don't choose a double-sided board unless you're forced into it. Start by running traces on the solder side only. If you run into too many intersecting traces you can always switch to a two-sided board. It's often surprising how many traces will fit on only one side, especially if your layout program has an excellent "auto-route" algorithm. It's

also worth remembering that jumper wires can frequently get you out of a bind on a single-sided board (and even on some double-sided ones!).

Tip #4

When possible, place mounting holes at half-inch increments from one another. Then, when you go to drill the mounting holes in the project case, you'll find that it's much easier to mark off half-inch distances than an odd number of 0.1-inch increments, the step size that most programs use.

Tip #5

For dual-sided boards, be sure to write "Solder Side" and "Component Side" right on the layout. This will help you later on when you have to determine the orientation of the clear artwork against the board. See Figure 1.

Tip #6

It's also a good idea to write the date and a version number right on the artwork—preferably on both sides of the board. This helps you keep track of multiple versions of the same project. I got hit by this once, and it took me nearly an hour to figure out that I had accidentally used an old version of my artwork on the bottom side of the board! See Figure 2.

Figure 1. Tip #5.

Figure 2. Tip #6.

Figure 3. Tip #7.

Figure 4. Tip #8.

Figure 5. Tip #9.

Tip #7

Most hams don't place a silk-screen layer on their boards. In its place, consider putting important information right on either the top or bottom copper layers. If you have the room, component names and/or values are often convenient to have right on the board. See Figure 3.

Tip #8

Try to mount all IC packages in the same direction, unless this violates one of the other rules mentioned above. If you are forced to mount one IC "upside-down," be sure to clearly mark pin #1 on both sides of the board (Tip #7). See Figure 4.

Tip #9

Change the schematic whenever it helps! It's amazing how many people seem to think a schematic is set in stone when they get to the layout phase of a project. If you can redefine connector pin numbers, or use one IC gate in place of another, it frequently simplifies the board layout. Just be sure you go back and update to print so you'll remember that you made the change later on.

Although I don't recommend it, some people tend to take this tip to an extreme—they actually lay out the board *before* they draw the schematic. See Figure 5.

Tip #10

Now here's one that is really simple, but again, it's surprising how many people never seem to think of it. Remember that all pads do not have to be the same size, not even all the pads for a single component. If you need extra room (to lay a high current

trace, for example) make some of the pads smaller. This is especially true for unused pads, which you may even be able to eliminate completely. See Figure 6.

Tip #11

Several times during the design, print out an exact-size copy of the layout, being sure to include the silk-screen layers even if you won't be using them. Place the actual components on this printout to make certain there's adequate space for everything. Pay particular attention to large capacitors, mounting holes for connectors, and any components whose templates you created yourself.

Also, be sure connector pin numbers line up correctly.

If you designed for a male DB25 connector, but the layout software put down a female DB25, your pin definitions are not going to be what you expect.

Tip #12

Place extra pads on unused connector pins or IC gates. You may not have a need for them later, but if your initial design doesn't work, they will make it much easier to modify the board further down the line. You may even want to include pads or component space for any "upgrades" that you might want to wire in later. See Figure 7.

Tip #13

If you don't use through-plated holes (as is the case with most hams), make certain that all the traces you run on the top layer can be soldered to the components on the top layer. For example, straight PCB-mounted connectors are frequently encased

in plastic in such a way that you can only solder them to the bottom side of the board—the top side of the pins are completely blocked off.

If this causes you a problem, there are two things you might try: Either mount them to a component a few millimeters above the board so you can get an iron in there, or use a via (through-hole) near the

Dealers: Your company name and message can contain up to 50 words for as little as \$420 yearly (prepaid), or \$210 for six months (prepaid). No mention of mail-order business please. Directory text and payment must reach us 60 days in advance of publication. For example, advertising for the April '92 issue must be in our hands by February 1st. Mail to 73 Amateur Radio Today, 70 Rte. 202 N, Peterborough, NH 03458

Figure 8. Tip #13.

problem pad. See Figure 8.

Tip #14

Once again, for those who don't use through-plated holes, keep vias to a minimum. You'll have to solder through every via that you design in, which is a pain in the neck. This is another handicap you may find with most auto routing routines, which tend to use vias like they're going out of style.

Tip #15

Consider creating your own personalized checklist of things you want to examine before you're finished with a layout. Before I came up with my list I

frequently forgot to size my mounting holes correctly, or to run an automatic check to verify all my trace routings.

Tip #16

Don't throw away all the "good old" design rules that you used when you laid out PCBs by hand. For example, you still should keep the analog and digital sections separated, be sure to use grounding planes where necessary, and don't make the traces too small for the expected maximum current load. Most software just isn't smart enough yet to check for stuff like this (but the way things are moving, it's only a matter of time!).

here is the next generation Repeater.

MARK 4CR

The only repeaters and controllers with REAL SPEECH!

No other repeaters or controllers match Mark 4 in capability and features. That's why Mark 4 is the performance leader at amateur and commercial repeater sites around the world. Only Mark 4 gives you Message Master™ real speech • voice readout of received signal strength, deviation, and frequency error • 4-channel receiver voting • clock time announcements and function control • 7-helical filter receiver • extensive phone patch functions. Unlike others, Mark 4 even includes power supply and a handsome cabinet.

Call or write for specifications on the repeater, controller, and receiver winners.

Building and Using N7APE's NiCd Zapper

An update.

by Marion D. Kitchens K4GOK

In the September 1992 issue of *73 Amateur Radio Today*, Ed Miller N7APE described a circuit for recovering NiCd batteries that have grown internal shorts. His article got my immediate attention because it seemed like a simple solution to a problem that plagues many of us. Most of us have numbers of just such NiCds. If you do much with NiCd batteries around the ham shack, then you will definitely want to build N7APE's circuit. Some hams have been known to burn out internal NiCd shorts by momentarily connecting them to an automobile battery. This can be dangerous, and is not recommended. N7APE's circuit can eliminate that danger and still recover the shorted NiCds. Furthermore, after clearing the short, the circuit will automatically switch into the charge mode and recharge the battery. A pretty neat circuit!

This article describes the experiences of two builders of N7APE's circuit, and relays the experience and knowledge they gained about recovering NiCds.

Building The Circuit

Gene WØDLQ and I both built "Zappers" according to N7APE's article. The original publication contained one error in the schematic: The correct value of R5 should be 560k, as per the parts list, and not the 560 ohm value shown on the schematic. More on optimizing the value of this resistor later. The unit shown in the photographs used an under-the-bench power supply (12 volt auto battery on a charger), while WØDLQ used a built-in AC power supply delivering about 17 VDC to the circuit. The unmarked diodes in the original publication are 1N914 or similar.

Being experimenters, both of us made minor changes in N7APE's circuit. First, as an operating convenience, a "reset" switch was added to discharge an internal cap (C7) so the unit could be easily reinitialized after recovering a NiCd. Second, some voltage dividers and sensing circuits were modified to allow use of different supply voltages. Third, a fixed voltage regulator chip was used in place of the LM317 regulator. My unit used an active LM317 current-limiting regulator in place of resistor current limiters. If the

LM317 current limiter is used, it requires a 1" x 2" heat sink. If you use the fixed resistor(s) at R1, they should be rated for 2 watts.

Gene and I could not resist adding a "zapping" LED to indicate that this function was happening. You have clear indications of the zap/charge mode via the red/green LEDs. We also added a switch to allow selection of 50 mA for charging AA size NiCds, or 100 mA for charging C or D size NiCds. The changes made in our circuits are shown in Figures 1 and 2.

Checkout and Adjustments

Several adjustments need to be made after assembly. The sequence of checks and adjustments shown in the sidebar is recommended. This list provides a sequence that allows for easy resolution of problems, should they occur. Note that it is easy to get the circuit "locked up" in the charge mode, so follow the checkout instructions carefully! You can "unlock" the circuit by pushing the "reset" switch.

Adjusting R13 for about 0.500 volts on

pin 6 seemed to help in recovering some of the very old NiCds. N7APE recommended about 0.300 volts, which should be fine for most users.

After getting the unit operating, optimization of the circuit is recommended. Optimization will result in the circuit delivering the maximum available energy to burn out the internal short, thus reducing the time necessary to recover a NiCd. The best method of optimization will depend on the resistor values and supply voltage in your particular unit. Try the easy way first.

The Easy Way

Short pin 5 of the IC to ground, and short across the battery box for the following operations. Adjust R10 for maximum voltage on pin 2 of the IC. Measure and record that voltage. This may cause the voltage on C1/C2 to increase and stabilize at the supply voltage. Check with a voltmeter. If the voltage is steady, you can optimize the unit the easy way. (If the voltage ramps up and down, you'll have to do it a slightly harder

Photo A. K4GOK's NiCd Zapper.

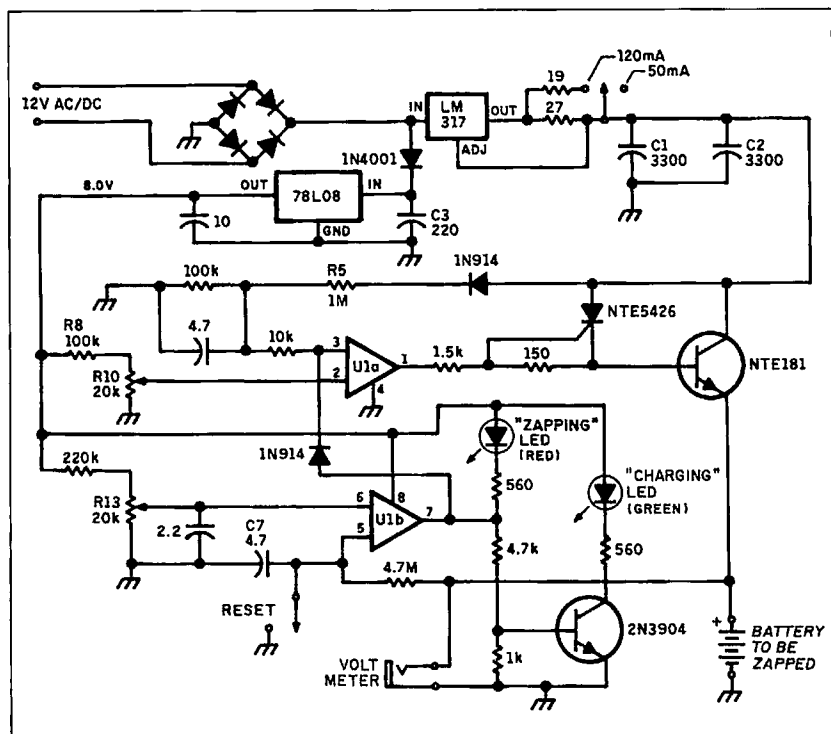

Figure 1. NiCd restorer from N7APE, as modified by K4GOK.

way, described below.) Once the voltage on C1/C2 is stable, measure and record the voltage on pin 3 of the IC; it should be less than that on pin 2. The voltage on pin 1 should be less than 1 volt. Next, adjust R10 until pin 3's voltage is just slightly less than that on pin 2. At this point, the voltage on pin 1 should be pulsing with very short pulses, and the voltage on C1/C2 should be ramping up and down.

The Harder Way

If adjusting R10 for maximum voltage on pin 2 does not stop the voltage ramping up and down on C1/C2, you'll want to make some changes in resistor values. The idea is to change either R5 or R8/R10 until you can get the ramping up and down to stop. In my unit I increased the value of R5 to 1.2 megohms, while Gene made R10 a 100k pot and replaced R8 with a jumper soldered permanently in place. The changes required will depend primarily on the supply voltage you use. In general, the higher your supply voltage, the larger the value needed at R5 or the smaller the resistor needed at R8. Make changes until you can get the voltage on C1/C2 to come up to the supply voltage and stabilize (no pulsing or ramping up and down) by setting R10 to maximum voltage at pin 2. Then adjust R10 as described above so the voltage on pin 3 is just slightly less than that on pin 2.

Check that the voltage on C1/C2 now ramps up and down. The unit will deliver the maximum energy to zap the NiCd when adjusted as described above. Remove the jumpers from pin 5 to ground and from

across the battery box. Now you are ready to put the zapper to use.

Zapping Some NiCds

Using the zapper is very easy. Put in the bad NiCd and turn on the power. The

"charging" LED will flash very briefly and the "zapping" LED will come on. If the power is already on when the NiCd is inserted, or if a recovered NiCd has just been removed, you will have to push the reset switch to reinitialize the circuit. The "zapping" LED stays on until the short is burned out. Then the zapper automatically switches to the charge mode and the "charging" LED comes on. Leave the NiCd in the zapper for the recommended charge time, or remove it and place it in a standard charger.

We had 16 very old NiCds on hand for learning to use the zapper. Eight of these were more than 20 years old, a good set to see just what the zapper would really do. All of these NiCds measured 0.000 volts, and obviously had internal shorts. We tried all eight NiCds for an hour or so without any signs of recovery. Additionally, we zapped all of them with the automobile battery technique, without success. The automobile battery technique had never failed before—it puts quite a large jolt of current through the cells. These NiCds were more than dead!

Finally, a NiCd was left overnight on the zapper, and the "charging" LED was "on" the following morning. Eventually, four of these eight NiCds were recovered by overnight treatment with the zapper. Let the zapper do its job, and don't give up on the NiCds too soon. Four of them never recovered, even after 24 hours on the zapper. We set those aside.

All eight of the remaining NiCds were recovered. These were not as old as the eight described above, but they were 10 or more years old, and unkept for most of that time. These recovered in varying time. Some in a

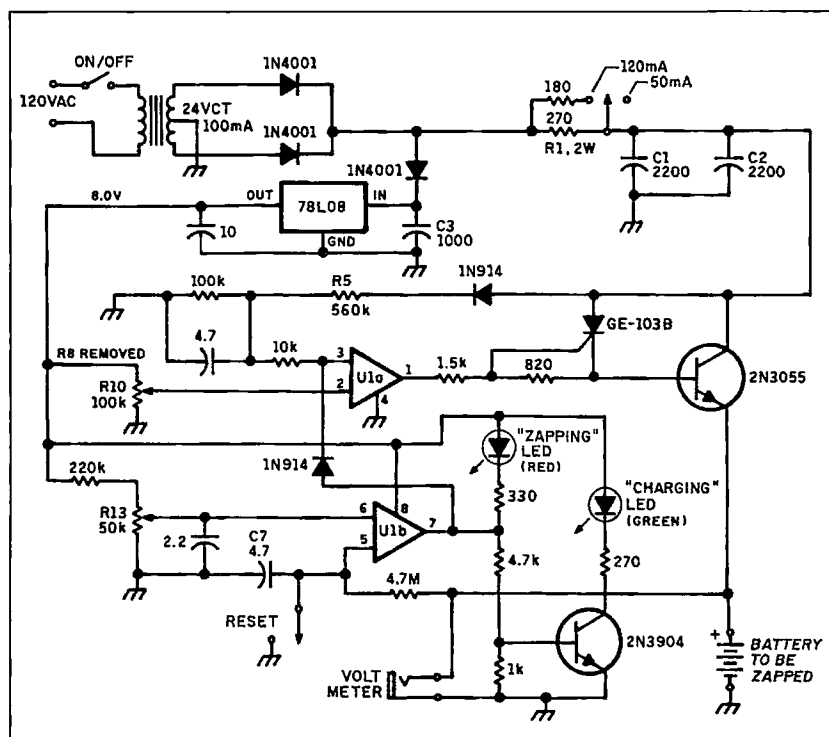

Figure 2. NiCd restorer from N7APE, as modified by WØDLQ.

matter of an hour or so, and a few required four or five hours to recover.

After recovery and charging, a number of the NiCds regrew their internal short. Some regrew the shorts while on a charger, unexpectedly. A short treatment on the zapper recovered these again, usually in minutes, instead of the overnight or several hours as initially required. All of those NiCds that initially regrew their internal shorts did so repeatedly. As they were re-zapped, it required less and less zapping time each cycle. It appears that with enough runs through the zapper they all might be fully recovered to hold a charge, although this has not been confirmed as of the writing of this article.

Several of the recovered NiCds displayed symptoms suggesting they had internal discharge paths, as opposed to internal shorts. This result exhibited itself when a zapped battery would recover in half an hour or less and would accept a charge, but would discharge to a low (not zero) voltage in less than 24 hours. About half to two-thirds of the 20+-year-old batteries had these symptoms.

More recently purchased NiCds (four to five years old) recovered nicely. I had only three NiCds in this category. They all recovered quickly and would hold a charge. No energy storage capacity test of these NiCds was done.

In recovery of old, shorted NiCds be wary of those that show unusually high or low voltages after charging. Experience suggested that those with fully charged voltages of more than 1.45 or less than 1.15 volts would eventually be "bad actors." They would either revert to internal shorts quickly, or would refuse to hold a charge for any significant time.

Note that the zapper will revert to the zapping mode if the NiCd voltage drops below the trip voltage set on pin 6. This allows you to leave a recovered NiCd in the zapper, and should it regrow its internal short while being charged, the zapper will automatically switch back to the zapping mode and re-zap the NiCd. This was observed a number of times on the 20+-year-old NiCds. This feature of N7APE's circuit was not recognized until it was experienced in practice. A nice feature indeed.

Conclusions

The N7APE designed circuit works and works well. It does indeed recover internally shorted NiCds in a safe and effective manner. N7APE did the ham community a fine service in designing the zapper circuit. NiCds as old as some investigated here could not be permanently recovered. However, those NiCds of more recent vintage were successfully recovered. Any ham who uses NiCds should construct this device and put it to use.

Acknowledgments: Thanks to my friend

Figure 3. PC board pattern and parts placement diagram for the NiCd Zapper.

Checkout Sequence

1. Remove all power from the unit.
2. Discharge C1/C2, C4, C5, C6, and C7 completely by temporarily shorting them to ground.
3. Remove the LM358 IC from its socket.
4. Put a shorting jumper wire across C1/C2 to ground, and leave it there until step 10 below.
5. Turn on power and verify that the voltage at the regulator output is correct.
6. Verify that the voltage across C3 is at least 2 volts higher than the regulator output voltage. If not, the supply voltage must be increased, or the value of R1 must be increased.
7. Measure the voltage across R1 (same as across C3) and calculate the current through R1. This current needs to be 50 mA for charging AA cells and 100-120 mA for charging C and D cells. If it is not correct, either the supply voltage or the value of R1 must be changed. The conditions of #6 above must still be met after any changes here.
8. Verify that pin 4 is at ground potential, and that pin 8 is at the regulator output voltage.
9. Adjust R13 for about 0.3 to 0.5 volts on pin 6, and set R10 to its midrange.
10. Turn off the power and remove the jumper from across C1/C2.
11. Discharge the capacitors as described in 1 and 2 above.
12. Put a shorting jumper across the battery box. Insert the LM358 IC in its socket, and apply power.
13. The "charging" LED may flash very briefly, and the "zapping" LED should come on.
14. Connect a voltmeter across C1/C2 and adjust R10 for the maximum voltage on pin 2 that still lets the C1/C2 voltage ramp up and down, as seen on the voltmeter.
15. Remove the jumper at the battery box. After about five seconds the "zapping" LED should go off and the "charging" LED should come on.
16. Push the "reset" button. The "zapping" LED should come on immediately, and after about five seconds should go off and the "charging" LED should come on.
17. Re-connect the shorting jumper at the battery box. The "charging" LED should stay on for five to 10 minutes, or until the "reset" button is pushed.
18. See the text for information about optimizing the zapping energy.

NOTE: It is safe to verify the battery charge current via a mA meter at the battery box as long as the "charging" LED is on. But do NOT try to measure the current when the "zapping" LED is on!

Gene WØDLQ for building a zapper as I was building mine, and for numerous exchanges of ideas, comments, and discussions. Without his involvement it is unlikely I would have tackled this fun and useful project. And, of course, many thanks to N7APE for designing and publishing the circuit!

[Ed. Note: Reprints of the original article, "NiCd Restorer/Charger" by Ed C. Miller N7APE, are available for \$3 each from 73 Amateur Radio Today, 70 Route 202 North, Peterborough NH 03458. Circuit boards for the original project are available for \$5 plus \$1.50 S&H from FAR Circuits, 18N640 Field Court, Dundee IL 60118.]

Backup Battery Monitor/Charger/Alarm

Be prepared for emergencies.

by J. Frank Brumbaugh KB4ZGC

The well-equipped ham station has one or more deep-cycle storage batteries to provide operating voltage during interruptions of commercial AC power. Battery backup is invaluable during emergencies, natural or man-made, and allows operation when commercial power outages are local in nature—when wind, ice or other elements down power lines, affecting small areas.

Storage batteries require care and must be maintained at full charge so they will be available immediately when needed. While delivering power to operate modern 100

watt solid-state transceivers, storage batteries must not be discharged by more than 60% of their ampere-hour capacity or they may be damaged. Replacing deep-cycle storage batteries can be an expensive proposition.

Because modern solid-state 100 watt transceivers draw about 20 amps keydown, at even the 33 to 50 percent duty cycle of SSB or CW this will limit emergency operation to 10 to 20 hours maximum if 100 Ah batteries are used. Normal operation is considered to be 10 percent transmit and 90 percent receive.

These transceivers often will not function properly at low voltage, and storage batteries can be damaged if discharged too deeply, so it is advantageous to be able to tell the state of charge of batteries at a glance instead of having to check the specific gravity of each cell with a hydrometer. Also, a visual or audible alarm to warn when the battery has been discharged by 60 percent—only 40 percent charge remaining—alerts the operator to cease operation or risk permanent damage to expensive deep-cycle storage batteries.

The battery monitor/charger/alarm de-

scribed in this article will:

- Monitor the state of charge of station backup batteries.
- Maintain batteries at full charge, preventing overcharging.
- Provide a visual and/or aural alarm that warns of low battery voltage.
- Indicate voltage and current supplied to the transceiver.

The Circuit

See Figure 1. This project includes a voltage-limited regulated power supply operated from the AC line and provides up to 3 amperes to maintain the batteries at full charge. Charging voltage is constant at the normal full-charge level, so the charging current drops as full charge is approached, and full charge is maintained with a trickle current. This charging voltage can be adjusted between approximately 10 and 15 VDC to accommodate lead-acid (13.8V) or lead calcium (13.2V, 13.5V maximum) deep-cycle storage batteries.

A separate connection is provided so an external charger can be used when greater than 3 amperes is needed to charge a partially discharged battery. Any standard automobile battery charger can be used, setting the charging current at no more than 10 percent of the ampere-hour capacity of

Table 1. Battery Condition Meter Calibration

Lead-Acid Battery		Lead Calcium Battery	
Color	Voltage	Color	Voltage
Red	11.6 and below	Red	11.6 and below
Yellow	11.6-12.0	Yellow	11.6-12.0
Green	12.0-13.8	Green	12.0-13.5
Red	13.8 and higher	Red	13.5 and higher

the battery. Internal circuitry will maintain the charging voltage to the battery at the nominal full-charge voltage level, regardless of the voltage supplied by the external charger, which will be 2 volts or more greater than that applied by the regulator to the storage battery. **WARNING: Do not fast-charge deep-cycle storage batteries!**

A pair of meters calibrated to indicate 20 VDC and 20 ADC full-scale monitor voltage and current provided to the rig when battery power is used.

A separate, suppressed zero, expanded-scale meter calibrated over the range of about 10 to 15 VDC allows immediate and constant indication of the state of charge of the station's backup battery. This meter scale is calibrated in bands of red, yellow and green, as explained in Table 1. The narrow yellow segment is based on the as-

sumption that solid-state transceivers may not operate properly below +12 VDC. The internal power supply is used to calibrate this meter. A DMM should be used for greatest accuracy. Colored markers can be used to produce the multicolored scale.

An alarm circuit is included to indicate when the battery has been discharged by 60 percent to the 11.6 VDC level. When battery voltage is above 11.6, the green

LED will be illuminated; when voltage falls to 11.6, the green LED goes out and the red LED lights. A piezo audible alarm sounds at this low voltage level unless silenced by the toggle switch controlling it.

A pair of fixed three-terminal regulators are included to provide +9 and +6 VDC for station accessories with outputs terminated in RCA jacks. An additional RCA jack provides regulated voltage from either the internal AC supply or the storage battery for accessories requiring this voltage.

Most small 12 volt relays have a coil resistance of 100-300 ohms and require 50 to 150 mA for operation. Because this current must flow through switch transistor Q4, the power dissipated is much higher than can be handled by any of the small signal transistors usually available (2N3904, etc.). Although at first glance it may seem

THE ANSWER IS GAP TECHNOLOGY • THE ANSWER IS GAP TECHNOLOGY

Q An Antenna with No Earth Loss?
A Yes... the answer is GAP's revolutionary technology.

If you're looking for an antenna that can out perform the others and give you the edge, you're looking for a GAP. The Challenger DX-VIII is the revolutionary design that answers your demands for multi-band operation and unequalled efficiency with low noise. This is the technology that eliminates Earth Loss. BAP delivers from an elevated feed, your power doesn't disappear into the ground. Put it up. Turn it on. No tuning. No frustration. BAP delivers everything but the hassles. And — GAP delivers at a fraction of the cost of the "so-called" competition.

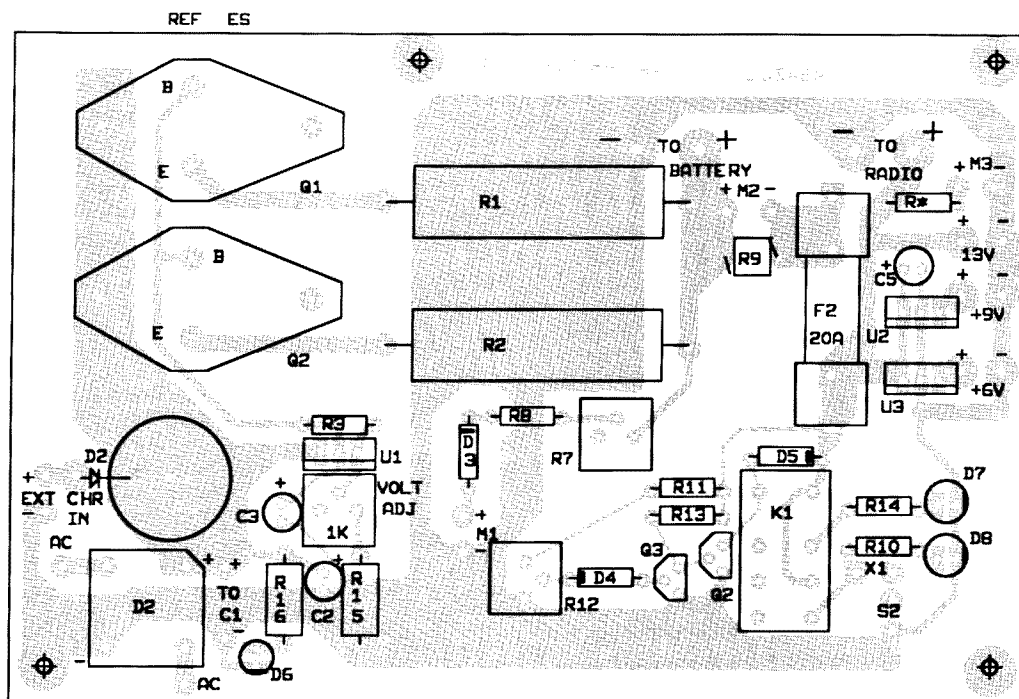

Figure 2. Circuit board and parts placement for the Backup Battery Monitor/Charger/Alarm. Note: If transistors Q1 and Q2 are mounted on the PC board, they must be heat-sinked. The transistors may be external to the board and wired back to the PC board.

charged to above fully charged condition of the storage battery is expanded over the full scale of the battery condition meter M1, making voltage (and charge level when calibrated) changes much easier to see.

The resistance of the meter multiplier I used was based on the 265 μ A full scale deflection of the small surplus meter I

used. Depending upon the full-scale current of your meter, the multiplier resistance can be determined, as explained above, for 5 VDC full-scale indication.

Final Adjustment

Apply AC power and set output voltage at 11.6 VDC, using a DMM for accuracy. Adjust R12 so the green LED D7 just ex-

tinguishes and the red LED D8 is illuminated. Operate S2 to check operation of the piezo aural alarm.

Increase output voltage to 13.8 VDC (lead-acid battery) or 13.5 VDC (lead calcium battery). Note that as output voltage is increased, the red LED D8 extinguishes and the green LED is illuminated. Now remove the power.

Parts List

C1	15,000 μ F, 50V electrolytic
C2	15 μ F 50V tantalum
C3, C5	22 μ F 15V tantalum
C4	0.01 μ F disc ceramic
C6, C7, 8	0.1 μ F 16V disc ceramic
D1	6A bridge rectifier
D2	20 ampere stud diode
D3	10V zener diode
D4	6.2V zener diode
D5	1N914, 1N4148, etc.
D6, 7	Green LED
D8	Red LED
F1	1 amp fuse
F2	20 amp fuse
J1, J2	2-terminal barrier strip, 25 ampere capacity
J3, J4	Binding posts, red and black
J5, J6, J7	RCA jacks (optional)
J8	Insulated terminal post
K1	12-VDC relay, SPDT
M1	Surplus meter, 200 μ A to 1 mA
M2, J3	0-1 mA DC meters
Q1, Q2, J2	2N3055 (on large heat sinks)
Q3	NPN small signal transistor (2N3904, 2N4124, 2N2222, etc.)
Q4	NPN 2N3053 (see text)
R1, R2	0.1 ohm, 5W
R3	240 ohm, 1/4W, 5%
R4	1,000 ohm pot, screwdriver adjust
R5, R6, R10, R14	1000 ohm 1/4W 5%
R7, 12	10k ohm trimpot
R8	15k ohm 1/4W 5%
R9	20 ampere shunt (see text)
R11, R13	1,000 ohm 1/4W 5%
R15, R16	1,000 ohm 1/2W 5%
S1, R2	SPST toggle or slide switch
T1	18-25 VAC secondary, 3A transformer
U1	LM317-T adjustable regulator
U2	7809 regulator (9 VDC) 1 amp
U3	7806 regulator (6 VDC) 1 amp
X1	Piezo alarm buzzer, 12-VDC

Pre-etched and drilled circuit boards are available from FAR Circuits, 18N640 Field Court, Dundee IL 60118, for \$9.50 plus \$1.50 S & H.

Connect J1 to the battery positive terminal and J2 to the battery negative. Also connect J2, or the negative terminal of the battery, to the station DC ground. Note the indication on the battery condition meter (M1)—it should be in the green area above 12 VDC. Apply power while watching ammeter M2. If 3A or less are indicated, the battery can be left on trickle charge.

If the battery condition meter M1 indicates low in the green or yellow area, do not apply power or you may blow the primary fuse or overheat the transformer. Instead, connect the positive lead of an external battery charger of the type used to charge automobile storage batteries to J8 and the negative terminal to the negative terminal of the storage battery. Set the charger for an indication on ammeter M2 of not greater than 10 percent of the battery's ampere-hour capacity—10A for a 100 Ah battery, for instance.

Note that the voltmeter M3 and the battery condition meter M1 indicate full charge for the type battery you are charging, and that D7 is illuminated.

Ignore the indication on the battery charger voltmeter if one is provided. It will indicate somewhat higher voltage than is required for a fully-charged battery, but the internal regulator in this equipment will hold the voltage applied to the battery to the proper level and will not allow the battery to be overcharged. Charging current will gradually be reduced as the battery accepts the charge, eventually tapering off to a trickle: under 1 ampere. At this time, or at any time thereafter, the external charger can be disconnected and the power applied to this equipment and it will then maintain the battery fully charged for use whenever needed.

Conclusion

The large-capacity deep-discharge storage battery used for backup power in the station represents a sizable investment. When properly maintained and used, it will provide satisfactory service for many years. Building and using this simple equipment will ensure that power will be available when needed. With the battery fully charged and connected to this equipment, which should be powered from the AC line and turned on at all times, no further attention is required.

However, as with any storage battery in backup service, monthly hydrometer readings should be taken of each cell and recorded, in accordance with the battery manufacturer's instructions. Water which may be evaporated from the battery over time should be replaced when necessary with *only distilled water*, available in numerous supermarkets and drug stores throughout the country.

WARNING: Do not use tap water or any bottled water except distilled water or the battery may be damaged or its capacity to hold a charge reduced.

AMATEUR TELEVISION

SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. Others may be retransmitting weather radar during significant storms. If it is being done in your area on 70 CM - check page 413 in the 91-92 ARRL Repeater Directory or call us, ATV repeaters are springing up all over - all you need is one of the TVC-4G ATV 420-450 MHz downconverters, add any TV set to ch 2, 3 or 4 and a 70 CM antenna. We also have downconverters and antennas for the 900 and 1200 MHz amateur bands. In fact we are your one stop for all your ATV needs and info. Hams, call for our complete ATV catalog - antennas, transceivers, amplifiers. We ship most items within 24 hours after you call.

HF/VHF Digital MFJ SWR Analyzer

MFJ Enterprises, Inc.
P.O. Box 494
Mississippi State MS 39762
Telephone: (800) 647-1800
Price Class: \$199.95

Over the past two years I have reviewed MFJ's SWR analyzers as they progressed through the evolution process. The first version required the use of an HF receiver for accurate frequency setting (or the use of a portable frequency counter). The next version included a built-in frequency counter that displayed the frequency as you tuned for lowest SWR. Both units were designed for operation in the HF area of 1.8 through 30 MHz.

The most recent MFJ SWR analyzer brings VHF capabilities. The MFJ-249 HF/VHF SWR Analyzer covers all frequencies from 1.8 through 170 MHz. If this device doesn't become one of the handiest helping hands around the shack I don't know what will.

What is an SWR Analyzer?

An antenna analyzer is used to accurately determine the SWR of an antenna at the shack feedline, antenna, tuner, or any point in between. No transmitted signal is required during measurements. This means no on-the-air tune-ups, something most of us wish would go away anyway. Adjustments to the antenna can be made while the unit is hooked up to the antenna, thereby giving instant results of adjustments.

Measurements are made by use of a variable frequency oscillator, an SWR measuring circuit, and a digital frequency display.

Advantages of a Small Unit

The MFJ-249 is completely portable for use in the field or in the shack (it operates on six AA batteries or an external AC supply). It can easily be used at ground level for verticals, on a tower for a directional antenna, and at any other antenna's feed point. Antenna SWR can be checked without returning to the shack.

In the shack, the SWR of your feedlines can be checked. After all, this is the SWR your transceiver will operate into.

Using the MFJ-249

First and foremost, read the manual before you use the analyzer. Although it is quite simple to operate, the analyzer can be damaged by improper use. The manual is

small, but it points out proper procedures that will assure correct usage. Probably the most important warning the manual gives is: DO NOT TRANSMIT INTO OR THROUGH THE ANALYZER.

The manual includes some general information about coax feedline losses and explains how high SWR increases these losses. It recommends further reading in the *ARRL Antenna Book*.

A sample SWR antenna plot chart is included, which can be copied for your use. Graph paper (my personal choice is 1/4-inch scale) works well for plotting, also.

In the Shack

I connected the analyzer to the various feedlines in my shack and tested each for the frequency of lowest SWR. I then made a record of this information for future reference. I also checked this newest set of readings with those of a year ago. All was still in order.

As a matter of curiosity, I now know why one of my 2 meter antennas has never

worked very well. The lowest SWR point is at 142.205 MHz and, unfortunately, the antenna is a sealed unit and not adjustable. Without the VHF capability of the new unit I could not have easily determined this.

I made a plot of the Cushcraft R5 (new last summer) and confirmed that no changes had occurred since installation. Interestingly, however, I found a large number of low SWR points between 60 and 115 MHz.

A couple of 2 meter HT antennas were checked and found to have SWR low points a little above the band. I have tried this test via other means in the past and observed similar results. It's interesting to watch the effect caused by objects in close proximity to these little antennas. When I waved my hand within a few inches of them the SWR would change from 1.2:1 to off the scale.

Have a feedline in the shack and not sure what it does? Just connect the analyzer and see where it operates.

Building and Adjusting a 75 Meter Dipole

The scenario for building a dipole antenna and using the analyzer for adjustments is quite simple. Using the formula $468/\text{frequency in MHz}$, a leg length of 60 feet each is determined. Note that few antennas will be exactly formula length, due to the environment in which they operate (i.e. proximity to power lines, other antennas, buildings, aluminum siding, etc.). For this example, the dipole legs are cut to 64 feet each (somewhat oversize, for adjustment purposes). Assemble the antenna using a center insulator as a feed point and haul it into place with a feedline attached.

Connect the analyzer to the feedline and check for the frequency of lowest SWR. In this case it is 3.585 MHz. As the antenna is meant to operate at about 3.9 MHz, some leg pruning will be necessary.

Leaving the analyzer connected, drop the antenna and prune 6 inches (12 inches at a time is OK until within 100 kHz of the desired frequency) from each leg and recheck for the frequency of lowest SWR. Repeat this process until the frequency of lowest SWR is within 25 kHz of the desired point. This completes the adjustments. Remove the analyzer and run the feedline to the

shack for use. By the way, it is not uncommon to be unable to reach an SWR of 1:1. However, 2:1 and below is quite acceptable for most purposes.

Note that the amount pruned from the legs must be equal on both sides. Additionally, when working on higher frequency antennas, you must prune less at a time. For example, on 17 meters a couple of inches at a time is appropriate.

In general, when the lowest SWR frequency is higher than desired, the elements (dipole legs in this case) are too short. If the frequency is below that desired, the elements are too long.

The advantages of antenna adjustments made in this manner are reduced QRM and the convenient lack of running back and forth between the shack and the antenna.

Antenna Tuner Adjustment

Want to eliminate another tuner-upper from the band? I sure wish everyone would! It's simple—just connect the analyzer to output #2 of a two-position self-grounding coax switch and your transceiver to output #1. The common output is connected to the input of your tuner.

To adjust the antenna tuner, select position 2 on the coax switch, set the analyzer to the desired frequency, and adjust the tuner until the SWR meter reading is at its lowest point. All this is done with no transmitted signal. Lastly, select position 1 on the coax switch and you are ready to transmit.

Frequency Counter

The MFJ-249 can be used as a frequency counter over its entire operational range. As with its predecessor, the 247 is not very sensitive and requires the use of a "times 1" probe for all but the most basic of frequency checks. However, all you have to do is put a rubber duck on the BNC connector and it's great for checking 2 meter mobile rigs and HTs. The readout is selectable from four to six decimal places.

Recommendation

Following the evolution of the MFJ SWR analyzers has been very interesting. They have all proved to be very useful and the MFJ-249 is the best yet. Having coverage from 160 through 2 meters is a definite advantage over the older models. For operational convenience, the SWR meter has been moved to just below the digital display and the non-sensitive controls moved to the top of the unit.

The MFJ-249 makes antenna work of all kinds easier, from tuning simple dipoles to adjusting traps on a triband beam to fine tuning HF mobile antennas. The analyzer is certainly a must-have device for Field Day, and with 2 meter capabilities it makes VHF mobile antenna adjustments a snap.

Since their inception, I have used MFJ SWR analyzers and would never go back to the old-fashioned method of transmitting a signal, taking a reading, going out to the

antenna and making an adjustment, returning to the shack, transmitting a signal, taking a reading, repeating, repeating, repeating! Being able to make all the necessary adjustments without returning to the shack is wonderful. As an extra carrot, I make no QRM while tuning my antennas. **73**

CIRCLE 71 ON READER SERVICE CARD

by David Cassidy N1GPH

US Digital Company's DVR 501A Simplex Repeater System

US Digital Co.
380 Rougeau Ave.
Winnipeg, MB
Canada R2C 4A2
Telephone: (204) 661-6859
Price Class: \$166

In the last few years, low-cost microchips that are capable of recording digitally have become available. Several companies have come out with products utilizing these chips in such things as contest voice recorders, repeater IDers, repeater voice mailbox systems, and what is called a "simplex repeater." Until recently, simplex repeaters have been mostly large and costly boxes, but US Digital Co. (strangely, a Canadian company) has released a palm-sized simplex repeater that works amazingly well for the price.

What's a Simplex Repeater?

A simplex repeater records a transmission, then rebroadcasts the recorded transmission on *the same* frequency. If you place the simplex repeater in a good location, low-powered stations are able to communicate over much greater distances, as long as you wait for the repeating of your transmission. One situation that springs to mind where a simplex repeater would be useful is in emergency rescue work, especially in remote and mountainous areas. Drive your simplex-repeater-equipped car to a high spot (or, in very remote areas, air-drop a simplex-repeater-equipped package), and everyone involved in the search will be able to communicate without the need for a manned relay station. Those involved with this type of communications might want to leave a simplex repeater permanently wired into their mobile rig.

There are other uses for a simplex repeater. You can set it up in announce mode so that instead of repeating whatever is heard, a pre-recorded message is broadcast at a pre-determined time interval. This would be useful as an automatic IDer, a low-cost way of adding voice announcements to your club's repeater, a way to test your own station's quality, a propagation beacon, or in dozens of other situations.

US Digital's DVR 501A

US Digital has come out with the smallest simplex repeater available. The entire unit fits into a case that easily disappears in a shirt pocket. The unit is powered by a standard 9

volt battery, and comes complete with a pre-wired cable that is suitable for use with ICOM or Yaesu HTs (if you've got an Alinco, Azden, Kenwood or other HT, a little rewiring of the plugs is all it takes). The repeater simply plugs into the microphone and speaker jacks. It's a simple matter to wire up additional plugs to make the unit function with any other transceiver.

US Digital Company's Simplex Repeater System, shown at actual size.

All connections and the single mini-switch are on the top of the well-made black plastic case. The case is so tight that I had a little trouble sliding the battery compartment cover back on after installing the battery. Once I was successful, no amount of squeezing or shaking produced the slightest sound or movement. This case is solid! The mini toggle switch is used to choose between repeat and

announce modes. There are also two LEDs to indicate when a signal is being received or transmitted.

Once you have the Simplex Repeater System connected to your transceiver and switched to repeat mode, anything that is received will be recorded and immediately rebroadcast. The digital recording chip that is the heart of the simplex repeater provides exceptional audio quality with a 3.2 kHz pass-band.

To set up the announce mode, you start in repeat mode. The announce mode takes the last message recorded in repeat mode and continues to broadcast it approximately every seven minutes. This means that you need two radios, one with the DVR 501A wired in, and another to send the announce message. After the message is recorded in repeat mode, you move the toggle switch over to "announce." The DVR 501A will now rebroadcast the message until you switch it off or back to repeat mode (or until the battery gives out).

In Use

The small size and battery power of the US Digital Simplex Repeater System brings one particular use immediately to mind: With this unit and an HT, you've got an instant, easily-hidden transmitter for your next foxhunt.

While I wasn't able to use the US Digital unit in an actual foxhunt, I found many other uses for this little box. Instead of keying up your local repeater over and over again to test that new VHF or UHF beam, a simplex repeater wired into your home station allows you to get a signal on demand from any line-of-sight location. I recently attended a hamfest where the sponsoring club used a simplex repeater to broadcast directions from all the major local highways. They set it up on a 2 meter simplex frequency, and it ran all weekend without a flaw.

US Digital's little simplex repeater is one of those gadgets that you never thought you needed, but after you get one, you wonder what you did without it. Its low cost and small size make it even more versatile.

PACKET & COMPUTERS

Number 12 on your Feedback card

Jeffrey Sloman N1EWO
75 Herriott Street
Franklin IN 46131

This column will be a break from the continuing series on asynchronous communications. I don't do this lightly, since I have gotten a lot of positive feedback on the series. I chose to take a break because it has become clear that I need to write something else first.

Those of you who receive *Radio Fun* have seen my column in that publication. Since *RF* is targeted to a beginning audience I have written about the operations aspects of packet, and packet etiquette in particular. After discussions with sysops and users, I have decided that the readers of this column also need some information on this very important subject.

The Problem

There are many packet operators who are technically savvy.

They have no problem whatsoever in setting up their stations, and are often heard on the local repeater offering useful advice to those trying to get started in packet. These operators are a valuable resource to packet—no question about it. Unfortunately, you will rarely hear these same hams helping others with their operating practices, and the abuse of the (inter)national packet network has become a critical issue.

The loosely composed network of stations that comprise the system we depend upon to forward packet messages throughout the US is being swamped by frivolous, redundant, and sometimes even illegal traffic. Personally, I don't believe that the hams who are causing the problem are doing so intentionally—I think it is ignorance at work. This, coupled with a lack of local instruction for beginners at packet, is what has lead me to write this column.

Illegal Messages

I'll start with the most problematic class of mistakes—messages that cross the line of legality. These messages threaten the existence of automatic forwarding as sysops (SYStem OPERators) decide that it is not worth the risk to their license to forward messages that contain traffic contrary to FCC regulations, and that it takes too much time to manually check the content of each message that passes through their systems. (Note: The ARRL is currently trying to solve this problem by changing the regulation to make it clear that the sysop is not responsible for the content of forwarded messages—a reasonable interpretation of the current regulations. This is a good idea, but the problem should be eliminated at the cause: the sender.)

These questionable or outright illegal messages are almost always "for sale" messages. In fact, "for sale" messages are responsible for many of the problems faced by the packet networks. The most troublesome of these messages are those that seek to sell non-ham-radio items. This is not allowed by FCC regulations. Anything offered for sale on ham radio, be it by voice,

packet, or any other mode, must be directly related to ham radio. Here is the problem: A recent informal survey of a week's traffic on a local PBBS (Packet Bulletin Board System) showed that about 75% of the messages were of the "for sale" variety. Of these, more than 50% were about computer equipment—including parts, components, and complete systems.

Now, I know that a computer can be used as part of a packet station, and parts like floppy drives and SIMMs (Single In-line Memory Modules) can be used in computers, but these are not ham radio gear. They have many other possible uses. A Kenwood 450-S, as a contrast, is obviously a piece of ham gear. The use of the packet network as an over-the-air computer swap meet has two obvious negative consequences. First, it creates a potentially hazardous situation for sysops, should the Commission decide to interpret the rules in an unfavorable way. Second, it clogs the network with traffic better left to landline BBSs, which are prevalent and readily available throughout the country. The bottom line on this type of traffic is that unless you are selling

a complete station—TNC, computer, and radio—it would probably be better to pass on packet as a method of advertising it.

Just Plain Silly

It is my own opinion that "for sale" traffic does *not* enhance the value of the packet network. However, I have talked with many hams who enjoy reading and responding to such messages. I am not here to tell you to stop trying to sell your ham radio gear via packet. On the other hand, if you are going to use packet to sell gear, please *think* before you do. When you see a message addressed to ALL@ALLUSA advertising a 70-foot crank-up tower—you *take it down*—you know that the sender:

A. Doesn't care about wasting bandwidth by sending his message to every BBS in the country when his tower could not be of interest to anyone outside of driving range of his QTH; or

B. Doesn't care enough to learn to address his message to just that area.

Reason A is just plain rude and reason B is not an excuse. If you are going to send a "for sale" message, start local, give it a chance,

then make a wider distribution. Yes, this is harder on you than sending an ALL@ALLUS message, but it is also courteous operation. Very frequently the item is sold to a local ham before the message even gets a chance to be forwarded outside your local area, anyway. If you are selling something that cannot be shipped, keep your traffic local. If you are selling something that is in demand, likely to sell quickly, keep your traffic local.

How do you address traffic to your local area? Each area has its own addresses that divide it up. The sysops in your area have these designations in their forwarding files so that traffic is distributed appropriately. If you don't know the address(es) for your area, leave a message for the sysop on your local PBBS asking. I am sure that he or she will be happy to provide the information. You may even be able to tell by looking at the traffic on the PBBS, since some of it is bound to be addressed to the local area.

More on Addressing

The idea that traffic should be addressed more selectively is not unique to "for sale" messages. Be-

fore you send ANY message, think about how it should be addressed. If you have a technical question about an AEA PK-232 MultiMode Controller—a very common unit—don't send your message to ALLUS! It isn't necessary. You are guaranteed to find the answer in your own state, probably your own town. By sending it to ALLUS, you just add to the burden of the already overburdened packet network.

On the other hand, if you have discovered a modification to the PK-232 that improves its AMTOR performance, and you want to share it, send it to something like PK-232@ALLUS. This is a perfect way to use ALLUS forwarding since it is a piece of technical information of use to all PK-232 enthusiasts. Notice, too, that I did not suggest addressing it to ALL, but to PK-232. This way, potentially interested hams will spot the message and will be able to use your wonderful new mod.

What's in a Name?

This brings us to message titles. If you have a good address—like in the example above, PK-232@ALLUS—then you just need to top it

off with a good message title. The point of the address and title of the message is to make sure that it gets to the right person. To accomplish this, the three parts must work together to get the traffic to its destination and then to engage the interest of the person you want to reach. Messages addressed to ALL@ALLUS, with titles like "hand-holds" just don't cut it. To complete the example from above, we might try something like:

PK-232@ALLUS Great AMTOR mod, just 3 caps

You can see where this kind of information will get it to your potential reader, and then entice them to read the message. Remember: You have 30 characters to work with in the subject line—use them well.

So, with a little thought and some desire to do the right thing, you can help make our packet networks a better place to operate. Cleaning up your packet act *will* help make a difference to everyone with whom you share the bandwidth of the packet network. Please, try to make a difference.

Next time we'll get back on track with our multipart series and I'll have some preliminary survey results. Till then, 73 de N1EWO. ✱3

DSP NOISE FILTER

NEW!

Savant™

...because knowledge is power!

A Packet Radio Program for the Macintosh®

- Written specifically for Macintosh® (not a port from DOS)
- System 7 compatible, 32 bit clean
- Implements the full Mac user interface, including:
 - Scroll bars in session windows (view previous traffic)
 - Edit menu with Undo, Cut, Copy and Paste commands
 - Saving and Printing of all or part of any session window
 - User re-sizeable split windows
- Supports multiple simultaneous connections each in its own window
- Change "channels" quickly by simply switching windows
- Simultaneous transmission and reception of packets in every session window
- Icons and fields in each window display that session's status
 - Packets outstanding and sent, retries, round trip time
- Stations Heard window displays the last 20 stations heard, and continuously updates the list while the window is open
- Monitor window decodes and shows all packet traffic
- Acts as a fully functional digipeater including the ability to assign an alias
- Operates with any TNC that implements KISS mode
- Fully compatible with Aaron Wohl's SoftKiss and Sigma Design Associates' PacketMac Modem

Using Operational Amplifiers

Operational amplifiers (op amps) were invented prior to the Korean War for use in analog computers; it's the math operations from analog computers that is meant by the term "operational." Interestingly enough, if you were to see the original Philbrick book on designing with op amps (copies are still in dusty book racks in college science departments, I am told), the circuits would look very much like those in modern op amp books. In this month's column we are going to look at the basic op amp circuits that are used in ham radio applications.

What are those applications? Well, the first that springs to mind is microphone preamplifiers. Also, you find these neat circuits in active analog filters, and in instrumentation circuits. Examples of the latter are Wheatstone bridges and antenna bridges where the minute DC signal produced across the detector can be amplified for display on an analog meter.

Figure 1 shows the basic circuit symbol for an op amp. The pin numbers given are for the popular 741 device, and this is considered the industry standard for a large number of products. Before hooking up some unfamiliar op amp, however, check the data sheet to see if it uses the "standard" pinouts.

There are two inputs on this device: -IN is the inverting input and produces an output that is 180 degrees out of phase with the input signal; +IN is the noninverting input and produces an output signal that is in phase with the input signal. Taken together, the -IN and +IN form a differential pair, i.e. allows us to build a differential amplifier. The output is single-ended with respect to ground.

Note that there are two DC power supply connections, and that neither of them is ground (see the inset for the typical op-amp power supply configuration). The V+ power supply is positive with respect to ground, while the V- power supply is negative with respect to ground. Some op amps also use either pins 1 and 5 or 1 and 8 for offset nulling or frequency compensation.

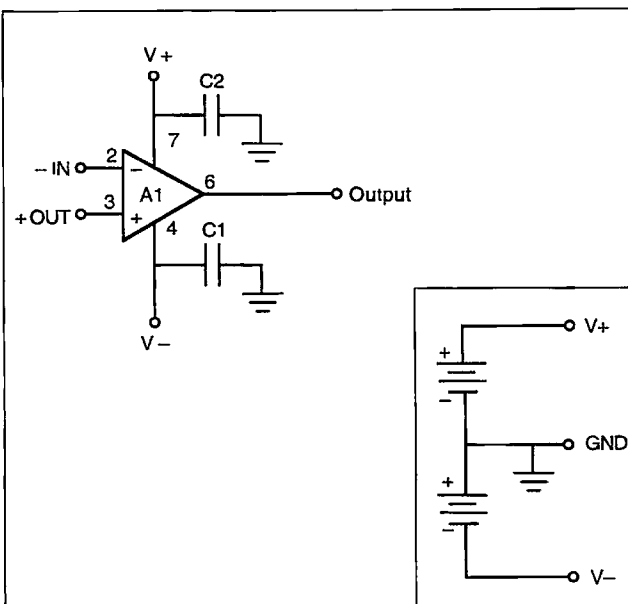

Figure 1. Typical op amp terminals, pinouts and power supply configuration. Pin numbers shown are the "industry standard" pinouts, and are from the 741 device. Check data sheet for any op amp other than 741, however, before connecting.

Op amps have very high open-loop (without feedback) gain (greater than 250,000 is typical). They therefore can be expected to oscillate all too easily. Even so-called "frequency compensat-

ed" or "unconditionally stable" op amps have been known to be rude enough to spuriously oscillate under the correct circumstances. Not good. As a result, most authorities recom-

Figure 2. Inverting follower circuit.

ment that the power supply pins be decoupled with capacitors that have a value that will produce a very low reactance path to ground. In most cases, a value from 0.1 μ F to 4.7 μ F is used for C1 and C2.

Note that in Figure 1 there is no ground connection on the body of the op amp itself. Input and output signals are ground referenced, but the only ground *per se* is in the DC power supply circuit (see the inset to Figure 1).

In most of the circuits in this article you will find the DC power supply ter-

minals deleted. That is done for graphic simplicity, but in really-working circuits you would connect V- and V+ as per Figure 1.

Inverting Followers

Figure 2 shows the *inverting follower* amplifier circuit. This circuit produces an output that is 180 degrees out of phase (i.e., "inverted") with the input signal. Thus, $V_o = -A_v V_{in}$, the standard notation (A_v denotes "closed loop voltage gain"). The value of the voltage gain is set by the ratio

Figure 3. Unity gain noninverting follower.

of the resistors in the feedback loop:

$$A_v = -\frac{R_2}{R_1}$$

The "-" sign in the equation denotes phase inversion taking place. The output voltage, as a function of the input voltage and gain, is therefore:

$$V_o = -V_{in} \left(\frac{R_2}{R_1} \right)$$

For example, let's assume that we want a gain-of-100 amplifier with an input impedance of at least 10k ohms. We therefore set input resistor R1 to 10k ohms (or higher), and then calculate the value of R2 that produces an A_v of 100:

$$R_2 = R_1 A_v = (10k \text{ ohms}) (100) = 1,000,000 \text{ ohms}$$

For situations where gain is de-

sired, make R2 greater than R1, but if you want to attenuate a signal make R2 less than R1. When R1 = R2 the gain is unity (1), and when R2 is a potentiometer the gain is 0 to 1.

Noninverting Followers

The noninverting follower produces an output signal that is in phase with the input signal, and comes in two varieties: unity gain (Figure 3) and greater-than-unity gain (Figure 4). The unity gain follower is used for buffering, isolating and impedance transformation. It gets the latter job from the fact that it has a very high input impedance and a very low (less than 100 ohms) output impedance.

The greater-than-unity configuration of Figure 4, like the inverting fol-

Figure 4. Greater-than-unity gain noninverting follower.

lower case, is a feedback network consisting of R1 and R2, but in this case the input resistor R1 has the "input" end grounded. The input signal is applied between the +IN terminal of the op amp and ground. In some cases, an extra resistor (R3) is used between +IN and ground in order to keep the output from saturating when the input line is opened. This situation occurs, for example, when the signal source is disconnected . . . as in when the microphone is removed from its jack.

The gain equation for the noninverting follower is a bit different from the inverting version, but is similar:

$$A_v = \left(\frac{R_2}{R_1} + 1 \right)$$

Note the absence of the "-" sign. It's not needed because the gain here is noninverting. The gain is one more than the resistor ratio. For low gains the extra "1" makes a large difference, but at high gains it is only a small error. For example, at a resistor ratio of 10:1 the gain is 11, and the difference between 10 and 11 amounts to 10 percent. But at a resistor ratio of 100:1 (as in the above example worked out) the gain is 101, so the error is only 1/100 or 0.01 (i.e. 1 percent). This little tidbit is not terribly useful unless you are stuck with standard value resistors. For making a gain-of-100 amplifier we can either find a 990k ohm resistor, or use the 1 megohm resistor and accept a 1 percent gain error.

Frequency Tailoring

Frequency tailoring is used in practical circuits to limit the signal spectrum, to limit noise, and to prevent the amplifier from oscillating. Capacitors can be used in simple op amp circuits to limit the frequency response. Consider Figure 5, a noninverting gain follower. The low end frequency response is limited by the combination of the input resistor R3 and capacitor C1. The -3 dB point is set by:

$$F_{-3dB} = \frac{1}{2\pi R_3 C_1}$$

For a microphone preamplifier, where the frequency response is typically set to 300-3,000 Hz, the combination of C1 and R3 would be set to 300 Hz or thereabouts. A combination of 100k ohms and 0.005 uF would do the trick. The upper end frequency response -3 dB point is set by the same equation, but with R2 and C2 substituted.

Single DC Supply Operation

A lot of ham applications of op amps do not like the dual DC power supply requirement of these little ICs. There is a way to operate them from a single DC supply, even though it is suboptimum from several points of view (e.g. output voltage swing, DC component on the output signal, etc.). Figure 6 shows how single supply operation can be obtained in either form of op amp circuit. The VDC power supply terminal on the op amp is

Figure 5. Frequency response tailoring with input and feedback capacitors.

Figure 6. Operation from a single DC power supply.

grounded, and the V+ terminal is connected to the positive DC power supply. A resistor voltage divider (R3 and R4) is used to bias the +IN input to some voltage V1. If R3 = R4, then V1 is one-half the DC supply voltage. This same voltage appears at the output of the op amp, so it's common to use a capacitor coupling to the "outside world." In some cases, where it is desired to keep the +IN input grounded for AC signals, a bypass capacitor is shunted across R4. This capacitor should have

a reactance that is less than R4/10 at the lowest frequency of operation . . . and the lower the better (I like R4/100 or less in my circuits).

Additional op amp circuits can be found in any of the many good books on the subject. Check either of my titles in the TAB/McGraw-Hill *Mastering* . . . series (one on amplifiers, the other on IC electronics). TAB can be reached toll-free at 1-800-233-1128 (in PA use 717-794-2191), or by mail at Blue Ridge Summit PA 17294.

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

Since the April 1993 "Hamsats" column and its focus on KITSAT-OSCAR-23, activity via this satellite has increased dramatically. During many passes over North America, the download request queue has been full, while many other stations stand by waiting to get in line to fill holes in incomplete files or to initiate new files. Pictures, voice mail, software, bulletins and messages from hams all over dominate the directory listings. With its higher-than-average low earth orbit of 1,300 km and high-speed 9600 bits-per-second (bps) frequency-shift keying (FSK) signaling rate, K-O-23 has become the most popular digital amateur satellite.

History

In 1989, the Satellite Technology Research Center (SaTReC) at the Korean Advanced Institute of Science and Technology (KAIST) began a joint effort with the UoSAT group at the University of Surrey in England to design and build a satellite for amateur radio communications and educational experiments. Sponsors in South Korea include the Ministry of Communications (MOC), the Ministry of Science and Technology (MOST), the Korean Science and Engineering Foundation (KOSEF) and Korea Telecom.

KITSAT-1, or KITSAT-OSCAR-23, was launched on August 10, 1992, from Kourou, French Guiana, as a secondary payload on the Ariane Structure for Auxiliary Payloads (AS-AP). This was the first Korean satellite of any kind and provided an opportunity for graduate students at KAIST to learn firsthand about satellite design and construction.

The primary objectives of the program were to acquire satellite development technology, enlarge the number of engineers experienced with spacecraft engineering, motivate

youth through space education, and widen the South Korean national interest on space science and satellites.

The experiments on board K-O-23 include the 9600 bps packet bulletin board system (BBS), the earth imaging experiment, a digital signal processing (DSP) experiment, and a cosmic ray experiment. All these systems have performed well.

The packet system has excellent transmit and receive characteristics. The power output is strong and correctly modulated and there have been few software crashes. The CCD (charge-coupled device) cameras have provided excellent black-and-white earth views. The DSP experiment has been heard "speaking" and the cosmic ray detector system has been providing data for study by those monitoring the telemetry. It is hoped that K-O-23 will continue to perform its radio and experiment functions for several years.

KITSAT-B

The SaTReC group is working on a new satellite scheduled for launch on August 31, 1993, once again from Kourou, French Guiana. Many of the experiments and activities planned for this hamsat are similar to K-O-23, but with improvements.

The transmitter and receivers will be similar to K-O-23 and will use the highly successful 9600 bps data transfer system with BBS operation. The main experiments will include a new camera system, an enhanced DSP experiment, an electron detector and an infra-red sensor device.

CEIS, or CCD Earth Imaging System, is designed to capture high and low resolution images of the earth using two separate cameras. The wide-angle system has a viewing angle of 76 degrees and a coverage of 1,022 by 990 km. The mean resolution is 2 km square and will provide black and white or color. A typical image file will require 250 Kb. The narrow-angle

Photo A. KITSAT-OSCAR-23 prior to launch.

camera has a viewing angle of 12 degrees and sees an area 116 by 115 km. Resolution is 200-m square with black-and-white pictures of 350 Kb each. Both cameras can be commanded to take a picture at the same time. This results in the narrow-angle camera effectively zooming in on the center of the image captured by the wide-angle unit. Image processing and compression will be performed on the satellite to provide fast downloading of pictures.

The DSPE, or Digital Signal Processing Experiment, will carry two units. The DSPE 30 is the primary system, with a TMS320C30 processor. The back-up unit employs a TMS320C25 chip and can be used in conjunction with the primary unit through a dedicated high-speed link when extra computational power is required. The system is similar to that on K-O-23. An enhancement over the previous system is the possibility of data transfer experiments at speeds greater than the 9600 bps hardware modem.

The LEED, or Low Energy Electron Detector, is designed to measure the electron flux in space and analyze the energy spectrum of the electrons in the auroral region. The system consists of four main components, including an electrostatic analyzer, spiraltron

electron multiplier, high-voltage supply, and control unit. LEED can detect electrons with up to 6670 electron volts (eV) in 16 steps, with a resolution of 20 percent. The signals from the detector are fed to an analog-to-digital converter and then through control logic to the satellite's data handling system.

IRES, or Infra-Red Sensor Test Experiment, incorporates special sensors manufactured and calibrated at KAIST. IRES is an instrument to monitor the changes in the current and voltage characteristics of an infra-red sensor in a space environment. The sensor will be placed in a thermally-insulated housing with a window that looks out the top of the spacecraft. The experiment's electronics will monitor both the temperature change of the housing (since the detectors must operate at very low temperatures) and the degradation of the sensor over time.

KITSAT-B will become KITSAT-2 after launch. At that time it will also receive an OSCAR number. Although August is only a few months away, there are other satellites that may be in orbit first, including ARSENE from France, RS-15 from Russia, and UN-AMSAT from Mexico. It's getting crowded up there. Amateur satellite activity has never been better.

Photo B. Kyeongil Choi at the KAIST control center in Korea.

Amateur Radio Teletype

Marc I. Leavay, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

It's an interesting time warp we write columns in. As I write these words, the Blizzard of '93 has just finished ravaging the East Coast. This "storm of the century" disrupted many plans, including a family affair we had been planning for several years. Our event has been rescheduled for June, just as this column will be published. Strange but true? You be the judge!

Anyway, that aside, here is a little note from Tom Vicinanza WA2UCH of Orlando, Florida, sent over the CompuServe network. Tom states that he read, with interest, my February 1993 column on getting an old Model 28 Teletype machine back on line. He has a Model 28-KSR about which he has some questions. Tom has a loop supply, made for the US Navy, which delivers 20 mA at 130 VDC. This loop supply appears to be an interface, and is labeled a "TeleTerminal." At any rate, his problems are where to put the current and where to connect the signal line. The machine has a polar relay, so the wiring will be different from that published in the February column. He believes that if the current is applied to terminal C5 (Black +) and C15 (Red -) that should be correct, but he doesn't see where to put the incoming signal from a decoder. Still C1 and C2? He asks how he can get his machine to run local, postulating that he could provide a closed loop to create the "sitting idle" effect, then connect the loop to the outputs of the TeleTerminal (or similar device) to print data.

Well, Tom, without knowing the circuit diagram of that "TeleTerminal," it is hard to say. Further, the circuit published in the February "RTTY Loop" was for a Model 28-RO, that is, Receive Only, as opposed to your Model 28-KSR, a Keyboard Send/Receive machine. Nonetheless, we can draw some conclusions. First of all, your polar relay needs a bias supply to keep the relay closed. This may well be provided by the TeleTerminal. The loop is interrupted by the signal, switching it on and off in step with the RTTY pulses. The interface, commonly called a "demodulator" or "terminal unit," normally takes care of this. Some terminal units provide an integral loop supply, which supplies the necessary loop current. Others terminate with an electronic switch, which serves to impress the RTTY signal onto an external loop. Whatever, you must determine the proper terminals to make the machine idle, then feed the loop signal into those terminals. Good luck, and I look forward to hearing from you with your results.

TUWIN Program

Another CompuServer is David Ventura KE0NA of Burnsville, Minnesota. He details purchasing an AEA CP-1 awhile ago, and building an RS232 interface for it using Radio Shack 1488 and 1489 chips. Built on a small board with jumpers to two wire-wrap sockets, the board plugs into the two sockets on the CP-1 board that use the old-style RS232 chips. He has been on RTTY for a few weeks and enjoys it very much.

Dave tells us about a program

called TUWIN. It works quite well and he is able to fill the buffer as the other station sends, which keeps the QSO going quite nicely. He notes that the mode is just what he expected it to be: good old-fashioned rag-chews, no talking to BBS computers, and real people. Well, Dave, I hope you will send along a schematic of the interface you put together, and I will pass it along to the multitudes. But for the time being, I took a look at that TUWIN program you mentioned, and it is an interesting little program.

Written by Wayne E. Wright W5XD, it is designed as an accessory to the WriteLog Windows logging program to allow Windows-based logging and RTTY for contesting, as well as general operations. TUWIN works with old-

want a copy of TUWIN, as mentioned in the June 1993 column.

The parent program, WriteLog, is available from Austin Code Works, 11100 Leafwood Lane, Austin, Texas 78750. Just be sure to tell them you read about it in 73 Magazine's "RTTY Loop," ya' hear?

Besides TUWIN, I continue to have several disks of RTTY and PC type programs available for a song. Collections #1 and #2 are RTTY and amateur radio programs; collection #3 is a bunch of archiving and utility programs for both DOS and Windows. Each collection will fit on a 1.44 Mb, 3.5" disk. One or two programs may be lost trying to cram them onto a 1.2 Mb 5" disk, and you will need to send a whole bunch of low density disks if

"Overall, this is a neat, if bare-bones, approach to using an older terminal unit on RTTY..."

style RTTY terminal units, like the HD-3030, MFJ-1229, or HAL ST-6, that do not do internal Baudot to ASCII conversion. It thus should not be used with multimode controllers like the PK-232 or KAM. With a split screen display, text to be transmitted is entered into the lower window, received text is displayed in the upper window.

The program uses the DTR and RTS lines on the serial port to indicate "transmit," with the lines being keyed about 500 mSec before the first character is sent, and continuing until about 500 mSec after the last.

Overall, this is a neat, if bare-bones, approach to using an older terminal unit on RTTY, with a spiffy Windows display. TUWIN is available on CompuServe, in the HamNet SIG, or can be obtained from me for the customary \$2 in US funds, 5" or 3.5" disk, and a STAMPED self-addressed disk mailer. Be sure to tell me that you

that is your requirement. Anyway, for any or all of the collection, send me sufficient media, a return mailer with sufficient postage affixed, and \$2 in US funds for each disk to be filled, to the above address. I am trying to turn these around within a few days so, if you have sent me a disk or disks and haven't heard in a reasonable period of time, drop me a note or E-mail message to make sure I received the original package.

See, the folks this month communicated with me via CompuServe, using my ppn, 75036.2501. Others have used America On-line, via MarcWA3AJR, and Delphi, also via MarcWA3AJR. You can do it too! I'll even register you for an America On-line sign-up kit, if you supply me with your name, address, phone number, and computer data. Sure, the U.S. Postal Service is fine, too, it's just so archaic!

Walking-Stick Yagi?

Hold it in your hand—it's a walking stick made of aluminum with rubber ends. But inside are all the elements of a 4 element yagi that goes together in 2 minutes. Ready for the T-Hunt. Ready to get your signal out of a hole into the repeater. No little bits to drop and get lost. Everything fits clean and tight and tough. 2meters \$79, 70 cm \$49. Weighs only 1 lb. Add \$6 Shipping & Handling. Info \$1.

Radio Direction Finding

Joe Moell P.E. KØOV
P.O. Box 2508
Fullerton CA 92633

Medal-Winning and Record-Breaking T-Hunts

Wichita, St. Louis, Toronto, Salem (Oregon and North Carolina), and Montreal have something in common. They are all cities with new and growing interest and enthusiasm for amateur radio direction finding (RDF) contests. In these hidden transmitter hunts (often called foxhunts or T-hunts), hams use special receiving equipment to find stations placed in unusual spots by other hams.

I learned about this new-found interest via letters and electronic mail from hams in each of these cities, plus others, in recent months. Many of them read about foxhunting for the first time in *73 Amateur Radio Today*.

Pack Your Toothbrush and HT

The 1993 Friendship Radiosport Games (FRG-93) are almost here. Here is your opportunity to take part in a world-class international on-foot foxhunt at a beautiful venue in Victoria, British Columbia. Kevin Kelly N6QAB/9K2FX, winner of the 1991 Friendship Games foxhunt, is expected to defend his medal, coming to the Games from his work assignment in Kuwait.

Foxhunters from Portland, Oregon (site of FRG-91), will be there, along with teams from California and Washington. Fifteen hams from Khabarovsk, Russia (site of FRG-89), will arrive in San Francisco on June 19 and proceed to Victoria for the contest and two weeks of international hospitality. Also expected are hams from Niigata and Morioka, Japan.

The FRG-93 foxhunt is expected to follow international standards, which

call for five "foxes," transmitting in sequence for one minute each on 2 meters. Total course length will be about two miles. RDF equipment is being provided by the sponsors for your use, so you can travel light.

In addition to the foxhunt, there will be optional CW sending/receiving contests, a special events station (callsign X07G), and a hamfest. At the hamfest you will find a swap meet, commercial displays, and a portable IPARN 2 meter satellite link across Canada.

Most events, including the foxhunt and CW contest, are scheduled for Saturday, June 26, at the spacious campus of Camosun College. An evening awards banquet will follow the competitions.

In recent conversations, I discovered that some hams think the Friendship Games are restricted to national champion foxhunters. Not so! Anyone who enjoys radiosporting is welcome. It's all for fun, in the spirit of international friendship and ham camaraderie.

For more information and to reserve your spot at FRG-93, write to FARS-Victoria, c/o Camosun College, Box 128, 3100 Foul Bay Road, Victoria, BC, Canada V8P 5J2. The information phone at the college is (604) 370-4420. Packet messages may be addressed to VE7KPV@VE7VBB.#ISLAND.BC.CAN.NA.

Be sure to indicate if you desire housing information. To find out more about what it's like to take part in international radiosporting, read "Homing In" for September 1991 and "Showdown in Portland" in the November 1991 issue of *73 Amateur Radio Today*.

A New Record for the Granddaddy Hunt

The Southern California All Day Mobile T-Hunt has taken place at least four times a year for as long as anyone can remember. There are only a few rules. The hider's 2 meter FM simplex signal must be copyable at the starting point. The T must be within the continental USA (no offshore islands, maritime mobiles, or trips across the Mexican border.) Lowest odometer mileage determines the winner; time doesn't matter in scoring. Nowadays, hiders and hunters are a bit disappointed if the hunt doesn't last at least 24 hours.

Just like other ham DXers, some hiders try to see how far away they can be. N6MI and WA6FAT set a record when they led the hunters to 8,351-foot Shuteye Peak near Yosemite National Park, 252 miles away from the starting point southwest of Los Angeles. For the February 27 All Day Hunt, Jim Forsyth AF6O and Eric Nansen N6YKE decided to immortalize themselves by increasing this record by 36 percent.

Jim told me that it was a lucky QSO that alerted him to the possibility of a record-breaking hunt. "The month before, a weekend hunt coincided with the January VHF contest. We ended up on Table Mountain looking for the hidden T, which wasn't there. While there, we decided to work a bit of the contest on 2 meters. We worked a guy who was putting in a strong signal from Utah. We got him to tell us where he was and how much power he was running."

"He told us that he regularly

Photo A. Kevin Kelly N6QAB/9K2FX looks over a new Japanese RDF set brought by Yoshiko Yamagami JQ1LCW to the 1991 Friendship Radiosport Games.

Photo B. Eric Nansen N6YKE and Jim Forsyth AF6O set a record by hiding 344 miles away on the Southern California All Day T-hunt.

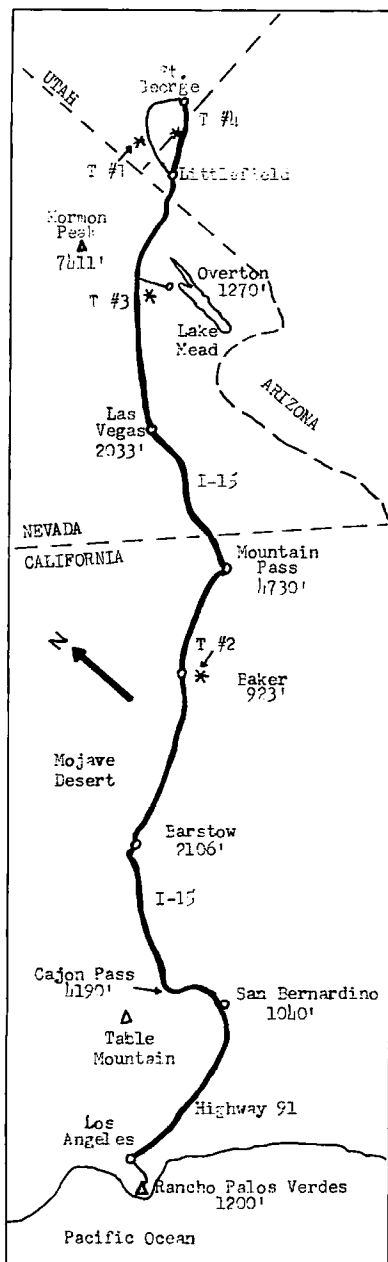

Figure 1. The shortest route to the four T's in the February 27 record-setting hunt lay mostly along Interstate 15, with lots of ups and downs. An accurate bearing at the starting point was crucial for success.

worked people in Los Angeles and Orange Counties from that spot," Eric added. "Jim told everybody that we had found our spot for the February 27 hunt on this outing, which led them to believe we would be near Table Mountain, only 59 miles from the starting point."

The record-setting spot is called Utah Hill. It's along a stretch of old US Highway 91 from Littlefield, Arizona, to St. George, Utah, passing by Jarvis Peak. "It looks right down on the Grand Basin," according to N6YKE. "Except for a little ridge in the valley, we had 2,500 feet of elevation over

everything between us and Las Vegas and beyond."

Would they be able to get a reliable signal across the 344 miles between this 4,724-foot mountain pass and the starting point? Jim obtained a 600 watt amplifier, a pair of car batteries to provide 28 volt power, float chargers and a generator.

On the day before the hunt, they went to the site to test with WB6ADC at the Rancho Palos Verdes starting point and N6XTJ on a hilltop in Orange County, keeping in touch on 40 meter mobile SSB. They transmitted 600 watts into a 15-element KLM Boomer yagi for an hour and a half with no success. Then they moved their set-up down the hill about 150 feet. Immediately, both WB6ADC and N6XTJ heard them clearly on 2 meters with their T-hunting quads.

A successful test doesn't necessarily mean a successful hunt, however. Over this distance, 2 meter propagation varies with time of day and weather, and the weather was changing. "On hunt day, we encountered snow at 3,500 feet on the way to the site," said Jim. "It turned out to be no problem driving there. There were three to four inches of snow, but it was melting fast. Propagation peaked before start time, but the hunters heard us OK."

Now the hunt was on. Transmissions continued at 600 watts for two hours. Then Jim and Eric shut off the generator and dropped power to 15 watts. Hunting teams that were taking the correct route would be crossing 4,250-foot Cajon Pass summit by that time, and could still hear the signal.

One Is Not Enough

At starting time, only the Utah Hill T was on the air. But participants in Southern California All Day Hunts are alert for the possibility of multiple foxes. Sure enough, T #2 appeared two hours later, long before any teams got close.

"We hid it Thursday morning on our way out and set the timer to come on at noon Saturday," said N6YKE. "It was on Kelbaker Road, 0.4 miles south of the freeway off-ramp at Baker, California."

The third T was on Highway 169, which goes south from I-15 to Lake Mead at Overton, Nevada. "It was hidden on the northeast side of a hill with

a beam pointing at Mormon Peak, a 7,411-foot mountain on the north side of I-15," said AF6O. "As you headed northeast on I-15, you couldn't copy the direct signal. All you heard was the reflection from Mormon Peak. Quite a few hunters got fooled by that."

The fourth T was near the I-15 Virgin River Gorge rest area in Arizona, nine miles beyond the Highway 91 exit to Utah Hill. "You had to get off at the rest stop and take a little dirt road on the opposite side of the interstate," said Eric. "People were 'sniffing' at the rest stop because it was pointing at a cliff there. One team took several hours before they found it."

Once they got T #4 in place, Eric and Jim drove down I-15 toward Las Vegas, listening to the chatter on the hunt frequency and on the 40 meter SSB coordination frequency. They met up with hunter J. Scott Bovitz N6MI around dark and all three decided to go to a casino for dinner.

"Sure," Scott confirmed. "As long as we were in Vegas, we might as well get three-dollar steaks."

"Then Scott decided to spend a few minutes on the roulette wheel," Jim said. "So he bought a few chips, won about five dollars, cashed in, and continued on the hunt."

"Scott said he thought T #1 was about 40 miles further up the road at one of the microwave sites," Eric continued. "So he wasn't in any big hurry. We also found out that he didn't have good maps of the area. We were following him from Vegas toward Utah and he stopped at a mini-mart. Jim realized why, so he jumped out, ran into the store and bought up all the Utah maps before Scott could get one."

As it turned out, N6MI found all T's in lowest mileage order (2-3-4-1), despite his lack of maps. He won the hunt with 460 odometer miles from starting point to T #1. Scott arrived at Utah Hill after midnight in a snowstorm. "It was just perseverance," he explained. "But it was a whiteout condition at the end. You could see better with headlights off than on."

Eventually, five of the six starting teams found the Utah Hill station. Four teams found all four T's, although some had poor mileage be-

cause they found them in the wrong order. "All T's were just off the pavement," said N6YKE. "We didn't make them too difficult, because we didn't want to be out forever."

Four transmitters in four states on one hunt! And you East Coast dwellers, who can drive through five of your tiny states between breakfast and lunch, remember we're talking big states here. Can other hiders top this? You can be sure some are studying topographical and relief maps trying to find a way.

Start Small, Have Fun

Don't get the idea that every hunt in Southern California is a marathon event. In Orange County, four clubs have begun monthly mobile outings just for beginning RDFers. They take place on various repeaters on week-day evenings, usually right after a club net, when listenership is high.

The hider makes short, frequent transmissions on the repeater input, urging every listener to get in the car and participate. Boundaries are small, usually just the county or part of it. After awhile, the fox station helps hunters by announcing smaller boundaries or giving other clues.

The idea is to insure that everyone finds the T in a reasonable period of time. To keep newcomers coming back, they need an evening of fun, not an ordeal. With a few short hunt successes, perhaps they will try longer-range hunts.

Pick Up Your Pen

I'm happy to get your letters telling about foxhunt activities in your area. I'm also pleased to see that new RDF equipment is becoming available in circuit board, kit, and assembled form, from a variety of individuals and companies. Beginning next month, "Homing In" will review some of these new offerings.

If you know of a new piece of fox-hunting equipment, want to tell about your experiences with home-brew or commercial gear, or want to pass along news of your local hunts, write to me at the address above. Send E-mail via CompuServe (75236.2165) or Internet (JoeMoell@cup.portal.com).

Scope It Out

Quite awhile back, I wrote about oscilloscopes and how great they are. If you're inclined to repair or build anything, you will find no tool more useful than a scope. You can find them at very reasonable prices, both new and at hamfests. Oddly, most hams I've talked to seem afraid of scopes, simply because they've never used them before and don't really know how to operate them. Besides, there are just so darned many knobs and buttons! This time, let's explore scopes in more depth and take a look at what the various features controlled by those knobs can actually do for you.

The Basic Beast

Essentially, a scope is a graphing machine. Specifically, it produces a fleeting graph of voltage over some specified period of time. The faster a signal it can graph, the "faster" the scope is said to be, and the more expensive it is. For HF circuits, a 50 MHz scope, which is pretty common these days, should be fast enough. For VHF and UHF, though, the cost of a capable scope will probably put it out of reach. Sometimes you can get lucky; I bought a 150 MHz scope at a hamfest for \$200. Sure, it was a risk, but the temptation was just too great to ignore. That scope lets me work on 2 meter rigs with great success because I can actually view the signals at 148 MHz! Some exotic lab scopes go to beyond 1 GHz, but you won't find one at a hamfest.

It's incredibly useful to be able to see how a signal changes over time, and it's not particularly hard to do, but that may seem hard to believe when you look at the front panel of your scope. It seems like there's enough there to pilot the space shuttle! So why are there so many confusing knobs and buttons on today's scopes?

One Size Doesn't Fit All

Scopes seem complicated because their screens are of finite size! And a pretty small size to boot. Let's face it, you really can't see that much at once. Most of the controls are there to let you scale the signal and scope parameters in such a manner that you can see what you want to see.

With the exception of a few new,

expensive LCD pocket models, oscilloscopes use cathode ray tubes (CRTs) similar to those in TV sets. So, naturally, there are some controls dedicated to adjusting the electron beam itself. You'll find brightness and focus, and those are self-explanatory. You might also find an astigmatism control. That one keeps the shape of the electron beam from getting stretched out as it sweeps up and down. Depending upon the signal you're looking at, you may have to adjust any or all three of these things to get the clearest view. On better scopes, though, the focus and astigmatism tend to stay put over wide signal variations, and some don't even need to have astigmatism controls.

There are many ways to use a scope, but by far the usual way is to graph voltage over time. (Other ways include frequency vs. time, two signals vs. each other, and more.) Because we're working with the good ol' Cartesian (X/Y) coordinate system here, our two basic parameters are horizontal and vertical. You move the CRT's electron beam up and down (X) in step with the incoming signal you want to view, and you sweep the beam from left to right (Y) at some predetermined rate. Let's look at the X (vertical) issues first.

Squeeze Me, Please

The object here is to squeeze the signal down so that all of it remains on the screen. Well, usually. Sometimes you want to see some small part of it which is near the middle or the top or bottom and you don't care if other parts are lost over the screen's edges. Either way, the VERTICAL AMPLITUDE control lets you make it as big or small as you want. Most scopes use a 1-2-5 arrangement for maximum convenience. What I mean by that is that the steps on the control are arranged like this: 100 mV, 200 mV, 500 mV, 1V, 2V, 5V, and so on. I can't explain why that arrangement is so nice to use, but if you try it, you'll see that it is; it just gives you steps that seem to fall where you want them. By the way, those numbers refer to the amount of voltage it will take to move the beam up or down one box on the graticule, which is the set of boxes drawn on the CRT's faceplate.

Concentric with the vertical amplitude control is a variable knob which lets you set values in between those you can select with the stepped knob. When turned all the

way up, the variable knob is said to be in the calibrated position, which means that the number you select on the stepped knob will be correct. So why would you possibly want to *uncalibrate* your oscilloscope? Usually, you only do that when you need to take a comparative measurement—say, for instance, that you want to see if one signal is just a little bigger or smaller than another. The reference signal is 3.47 volts peak-to-peak, so neither of its peaks hits any of the graticule markings. Now you look at the other signal and, gee, it kinda looks the same, but it could be a little different. If you go back to the reference signal and use the variable control to reduce it until its peaks line up with some of the graticule markings, it becomes much easier to tell how another signal, or the same signal at a later time, compares. Just be sure to reset the variable control to its calibrated position when you're through. I can't tell you how easy it is to forget to do that and spend the next two hours going around in circles because you're working with an incorrectly calibrated instrument!

Going Up?

Somewhere near the amplitude control (also sometimes called the "attenuator") you'll find a position control. All this does is let you move the entire waveform up or down in order to line it up with the graticule. It does not make the signal bigger or smaller; it just shifts its position. You may also find an "invert" button. That lets you flip the waveform upside down. It can be handy if it helps you to visualize what is going on in the signal, and it is especially useful with multiple-channel scopes (which we'll get to later) because it lets you subtract signals from each other in order to see tiny differences between them.

AC/DC

Not the rock band. This button lets you select the type of coupling between the probe and the scope. If you select DC, any voltage level, even a non-changing one, will move the trace on the CRT. That's handy for checking DC voltages and offsets. If you pick AC, though, a capacitor is placed in series with the probe, and the scope will only display *changes* in the signal. Ironically, that's most useful on DC signals! You use it when you want to see, for instance, how much ripple there is on a power supply's output. If you're testing a 12 volt supply, you can't see 100 mV of ripple because the trace would be way off the screen at that scale. But, with AC coupling, the 12 volts are blocked, and you can set the amplitude control as sensitive as you need it.

Then, 100 mV of ripple can fill the entire screen!

A Probing Topic

No discussion of an oscilloscope's vertical stages would be complete without talking about the probe you use to connect the scope to the circuit you're examining. It may seem obvious that the probe is nothing more than a piece of wire, but that often isn't the case. Most probes are either 10:1 or switchable 1:1/10:1 types. The ratio refers to the amount the probe will attenuate the signal before it enters the scope's input stages.

Why the heck would you want to do that? Two reasons: First, the signal may be so big that, even with the amplitude knob set to its highest range, the waveform won't fit on the screen. That happens, but not all that often with today's solid-state gear, which uses fairly small signals in most stages. Second, reducing the signal right at the probe raises the apparent input impedance of the scope by the same factor. So, if your scope has a 1 megohm input impedance and you use a 10:1 probe, your circuit sees a 10 megohm input impedance instead of the 1 meg it would see with a direct connection. That is very handy because it avoids loading down the circuit and the false readings that can result. In practice, it usually pays to use the 10:1 setting and make up for the gain loss by increasing the scope's sensitivity with the amplitude control. Of course, if the signal is extremely small, you may not be able to do that, and you'll have to switch to the 1:1 setting on the probe.

Passive Resistance

The probe's attenuation is provided by a simple two-resistor network. There's a resistor in series with the tip and another to ground at the first one's other end. The scope connects to where the two resistors meet.

If you look at a 10:1 probe, you'll notice a small screwdriver adjustment. This lets you set the probe's capacitance to match that of the scope's input stage. If it's set wrong, signal peaks will be either exaggerated or squashed down. To make sure it's set right, connect the probe to the scope's CALIBRATE pin. That pin provides a square wave, usually at about 1 or 2 kHz. All you do is set the probe to 10:1 (if it's switchable), set the scope's coupling switch to DC, and turn the probe's adjustment until the tops and bottoms of the square wave are as flat as you can make them. If your scope has no CALIBRATE pin or its oscillator is broken (as it is on one of mine), you can use any rea-

sonably clean 1 kHz square wave. If you change the probe to another channel or use another probe, you'll have to recalibrate it, because no two input channels are exactly the same, not even on the same scope! It always pays to check.

That should about cover all of the vertical controls on most scopes, with the exception of a few found on multiple-channel units. Next time, we'll get into those and the really fun part. Now, let's look at a letter.

Dear Kaboom,

What's the difference between a linear amp for FM/CW and one for SSB? Can I use a CW-type amp on 50-MHz SSB?

Signed,
Wanna Talk

Dear Wanna,

We hams have a habit of calling any big RF amplifier a "linear" amp. Unfortunately, not all amplifiers are truly linear. Those made for FM or CW don't have to be because the exact waveform, and its precise amplitude changes, don't carry intelligence. So, you can get away with lots of distortion and then clean it all up with a filter before you send it to the antenna. That's precisely

the technique used in walkies and CW transmitters, and not just because it's cheaper. It's also considerably more power-efficient. For AM and SSB, though, you need true linearity. That means that the output power of the amp must go up and down exactly in step with the input signal's amplitude changes. After all, those changes represent the modulation you want to transmit in the first place! The basic difference between the two types lies in how the power element, be it tube or transistor, is biased. A truly linear amplifier has enough bias voltage on the element that both the positive and negative peaks of the incoming signal are accurately amplified and not clipped off. So, if your amplifier is truly a linear amplifier, it should work fine on SSB. If you're not sure, try running it into a dummy load and listening with another rig. If the audio is horribly distorted, the amp will need some modification to be useful on SSB. By the way, you should never run an SSB amp anywhere near full power on FM, not because it won't work, but because the constant full power demanded by this mode probably will overheat and destroy the amp!

See you all next time.

RANDOM OUTPUT

Continued from page 88

round attendance figure. Let's be generous and assume that two-thirds of those tickets are paid at the pre-registration price of \$11 and only one-third are bought at the door for \$14. That's another \$360,000. There were 48 pages of advertising in last year's program book, at a round figure price of \$780 per page, so \$37,440 is the take on that.

Adding up the figures, we come to a very conservative income estimate of \$898,515. Since most of the staff working the hamfest are volunteers, the expenses are a lot less than they would be for another industry's trade show. Renting the Hara Arena, security, advertising, printing of tickets and programs and paying for some of the speakers' travel and lodging are the only major expenses.

As long as everything is on the up-and-up, I'm the last person on earth who would begrudge any person or organization from making as big a profit as they can (I'm a capitalist to the very core). I honestly don't care what happens to the profits, and frankly it's none of my business. Since none of that money seems to be spent on improving the conditions and services of the Hamvention, I simply wonder where it's all going.

What really put the icing on the cake for me was my dealings with the guy who ran the exhibitors' booths last year. After 73 had spent something like 20 years in the same spot, he wrote to me and told me that because

our check had not been received in time, we would not be able to retain the same booth space. In fact, after calling this gentleman, he informed me that he had already given the booth to another exhibitor, and he had already told the other exhibitor the good news. All the time, this gentleman assured me that the fact that our two booths, on the end of a row, has restricted them from forming a two- or four-booth "end cap" had nothing to do with 73 losing the space. Of course, you can probably guess what type of booth arrangement the new tenants were planning. Though it took many phone calls and some smooth talk, 73 finally got the booth, but it left a sour taste in my mouth. I'd rather not do business with a company that treats its customers so shabbily. I wonder if Kenwood, ICOM or Yaesu would have their booths taken away without so much as a courtesy phone call.

The unfortunate thing about all of this is that this year's booth chairman seems like a very professional and pleasant chap. In fact, I'm sure that all of the volunteers and club members who work the Hamvention are nice folks. If it weren't for reason #1, I probably would have given Dayton one more try. Nonetheless, after talking it over with Wayne, we decided that the liabilities of exhibiting at Dayton far outweighed the benefits. We'll rethink our decision from year to year, but I'm happy with what we're doing.

After all, would you be willing to pay a higher cover price or subscription rate, just so 73 could have a booth at Dayton? I thought not.

Ham Doings Around the World

JUNE 5

NORWICH, CT The annual Ham Radio Auction sponsored by the Radio Society of Norwich, will be held from 10 AM until sold out, at the Waterford Senior Citizen Center, Waterford Municipal Complex. Bring your equipment to be auctioned. Talk-in on 146.071.67 rptr. Contact **KA1BB** at (203) 739-8016.

SOUTH BURLINGTON, VT Come to the South Burlington Middle School on Dorset St., to enjoy the Northern Vermont Mid-Summer Hamfest. Time: 8 AM-3 PM. VE Exams at 2 PM. Talk-in on 145.47 (-600) or 146.85 (+/-600). Contact **Joe Tymecki N1DMP**, (802) 893-6458 or **Mitch Stern WB2JSJ**, (802) 879-6589.

JUNE 6

CHELSEA, MI The Chelsea Swap & Shop, sponsored by the Chelsea ARC Inc., starts at 8 AM at the Chelsea Fairgrounds. Talk-in on 146.980-. Contact **Gary R. Widmayer N8AYY**, P.O. Box 325, Manchester MI 48158. Tel. (313) 428-9398.

MANASSAS, VA The Ole Virginia Hams ARC will sponsor the Manassas

Hamfest/Computer Show at the Prince William County Fairgrounds. Open to the public at 8 AM. Talk-in on the Manassas rptr., 146.371.97 and 223.06/224.66. Commercial vendors contact **Woody KD4DEG** at (703) 368-5180. For info, call **Mary Lou KB4EFP**, (703) 369-2877.

NEWINGTON, CT The annual Amateur Radio and Computer Flea Market, sponsored by the Newington AR League, will be held from 9 AM-2 PM at Newington High School. Guided tours of ARRL headquarters and W1AW. VE Exams (no walk-ins); SASE to **Susan Fredrickson WM1B**, P.O. Box 165, Pleasant Valley CT 06063. For info and Flea Market reservations, contact **Jim Carney KA1TAF**, c/o NARL, 34 Meadow St., Newington CT 06111; Tel. (203) 673-0884; (SASE for confirmation).

PRINCETON, IL The Starved Rock Radio Club Hamfest will be held at the Bureau County Fairgrounds, starting at 6 AM. Talk-in on 146.355/955. Contact **Mark Tondi N9OVD**, RRI Box 34, Peru IL 61354. Tel. (815) 446-4342; or **Nils Barto, Jr. N9PLJ**, 2238 Schuyler Dr., Peru IL 61354. Tel. (815) 224-1299.

JUNE 12

BANGOR, ME A Hamfest, sponsored by the Pine State ARC, will be held at the Hermon Elementary School from 8 AM-1 PM. Flea Market. VE Exams. Contact **Roger W. Dole KA1TKS**, RR #2 Box 730, Bangor ME 04401. Tel. (207) 848-3846.

LOVELAND, CO The Northern Colorado ARC will present "Superfest XV" at the Larmer County Fairgrounds, 700 S. Railroad. Open to the public at 8 AM. ARRL VEC Exams (call **Rick Hubbard WA0DDC**, (303) 353-3577). Talk-in on 144.515/145.115 and 146.251.85. For table reservations, contact **Orlin Jenkins K0OJ**, 2101 5th St., Greeley CO 80631; Tel. (303) 353-7094. For details, contact **John Schmidt NK0R**, 1001 King Dr., Loveland CO 80537; (303) 663-7581.

MARMORA, ONT., CANADA Eastern Ontario Hamfest, sponsored by the Marmora ARC, will be held at 9 AM at the Marmora Curling Club. Talk-in on VE3TZW 145.41/144.81 rptr. Info and table contact: **Paul VE3UUM**, (613) 472-3449.

WINSTON-SALEM, NC The Winston-Salem Hamfest/Computer Fair will be

held at Lawrence Joel Veterans' Coliseum Annex, 9 AM-5 PM. Talk-in on 146.04/64. Send SASE to **B.J. Honeycutt**, Winston-Salem Hamfest, P.O. Box 11361, Winston-Salem NC 27116. Tel. (919) 723-7388 (24 hrs).

SPECIAL EVENT STATIONS

JUNE 12

WALLINGFORD, CT Grand Lodge A.F. & A.M. of CT amateurs will operate *WT1R* 1300Z-2100Z at the Masonic Home and Hospital, to celebrate Grandmaster's Day. Operation will be in the lower General portion of the 80-10 meter bands. For QSL, send SASE to *Bruce Backer*, Box 5028, New Haven CT 06525.

JUNE 15-18

LONDON, ONT., CANADA The London ARC will operate *CJ3-LON* from a hot air balloon on one of the following evenings: June 15, 16, 17, or 18; and the morning of June 19th, to celebrate the 200th Birthday of London, Ontario. Frequencies: 146.52, 446.00 simplex, and *FSTV* 439.25 TX only. For commemorative QSL, send QSL and SASE to *Anthony Drawmer VE3-SOU*, 55 *Briscoe St West*, London N6J-1M4 Ontario, Canada.

JUNE 18-20 and 25-27

WASECA, MN June 1993 marks the 70th year that E.F. Johnson Co. has manufactured radio and electronic components. To celebrate this historic event, the Viking ARS will operate a SE Station using Edgar Johnson's original call-sign, *9ALD*. If it is unavailable, *WA0CJU*, the club call of the Viking ARS, will be used for the duration of the event. Operation will take place on all non-WARC bands from 160-10 meters using a mixture of AM, SSB, and CW. Send an 8 x 11 SASE for a QSL card and special certificate, or a letter size SASE for the QSL card. For more details, call the 24-hour-hot-line, (507) 835-6612. Send requests to *E.F. Johnson Co.*, ATTN: 70th Anniversary Special Event Station, P.O. Box 1249, Waseca MN 56093.

JUNE 19

SPIVEYS CORNER, NC Triangle East ARA will operate *AC4QD* 0300Z-1200Z, to celebrate the 25th annual Nat'l 'Hollerin' Contest. Frequencies: CW 7.135 and 21.405; Phone 28.335 and 14.260. To get a certificate, send QSL and SASE to *TEARA*, 209 N. Third St., Smithfield NC 27577.

YUMA, AZ The Yuma ARC will operate a Special Event Station in commemoration of the 50th Anniversary of the US Army Yuma Proving Ground. Operations will be in the 15 and 20 meter General, and 10 meter Novice phone subbands, from 1500Z-2400Z. For a certificate, send QSL and a 9 x 12 SASE to *Operator CBA or YARC*, P.O. Box 7077, Yuma AZ 85366.

JUNE 19-20

ARCADE, NY The Pioneer Radio Operators Soc. (PROS) will operate *W2CRY* from the Curriers, NY Railway Station, to celebrate the one millionth passenger carried by the Arcade and Attica Steam Railroad. Operation will be in the General SSB/CW 10, 15, 20, 40, and 75 meter bands with 2 meter "rail-mobile" operation on 145.390 MHz rptr. SASE to *W2CRY*, 9765 S. Protection Rd., Holland NY 14080, for a special QSL.

Ocean Challenge

In 1853, the 200-foot clipper *North-ern Light* set the sailing record from San Francisco to Boston, 15,000 miles, in 76 days and six hours. Rich Wilson WA1BZE and Bill Biewenga aboard the 53-foot trimaran *Great American II* are trying to break that record.

In January of this year, the science coordinator of the Staten Island school district, where I teach, invited me to participate in Ocean Challenge with my ham radio classes. I was able to make contact with Lyon Osborn in the Boston home office. He was the telephone link with Bill and Rich once they set sail in January. He and I arranged for the initial ham radio contact to take place on March 26th.

A curriculum book was provided to us which included lessons about longitude and latitude, boat structures, weather, teamwork, geography, and communications. The children enjoyed the preparatory lessons on courage and perseverance. They were fascinated to learn that Rich has a severe case of asthma. He must take medication four

times a day. This is the reason that the American Lung Association is one of the sponsors of Ocean Challenge.

We spoke in class about what kind of personality characteristics we expected to find when and if we got our chance to speak with Rich. I explained to the children that three years ago Rich was the skipper of the *Great American I*, when he attempted the same voyage. On Thanksgiving Day in 1990 the boat capsized and was lost when a 50-foot wave swept over it during stormy seas. He and his co-skipper were lucky enough to be rescued that night by a cargo ship heading towards New Zealand. This has prompted many people to ask him why he would want to take the risk again.

For days prior to the contact, the children in my 6th, 7th, and 8th grade radio classes wrote down questions that they would like to ask Rich. There was a lot of good, creative thinking going on. I chose the best questions, and made arrangements for those children to stay after school for the prearranged contact on 20 meters.

When we finally were able to establish a contact with WA1BZE/MM we were all quite excited. Each child lined up at the rig to ask his or her question. One of my youngsters, Jordan

Photo A. Following the *Great American II* on a map was an activity the kids looked forward to.

KB2PYS, asked about the kinds of birds that they had seen. At the time of the contact they were 45 degrees west of Cuba. Rich is an extremely verbal

operator and he went into great detail about the albatrosses they had spotted in the South Seas. He described them as unique, graceful birds with wing

INTRODUCING THE UNIVERSAL M-400

A totally new concept in code / tone readers!

- A RTTY-reader and tone-decoder in one!
- Easy to read two-line 40 character LCD.
- No computer or monitor required.

- Baudot
- Sitor A/B
- ASCII
- Swed-ARQ
- FEC-A
- FAX
- POCSAG
- GOLAY
- ACARS
- DTMF
- CTCSS (PL)
- DCS (DPL)

Forget the limitations you have come to expect from most "readers". The self-contained Universal M-400 is a sophisticated decoder and tone reader offering an exceptional range of capabilities. The SWL will be able to decode Baudot, SITOR A & B, FEC-A, ASCII and SWED-ARQ. Weather FAX can also be decoded to the printer port. The VHF-UHF listener will be able to copy the ACARS VHF aviation teletype mode plus GOLAY and POCSAG digital pager modes. Off-the-air decoding of DTMF, CTCSS (PL) and DCS is also supported. The M-400 can even be programmed to pass only the audio you want to hear based on CTCSS, DCS or DTMF codes of your choosing. The M-400 can run from 12 VDC or with the supplied wall adapter. The American-made Universal M-400 is the affordable accessory for every short-wave or scanner enthusiast.

Only \$399.95 (+\$6 UPS).

spans up to seven feet. Rich also described the beautiful color of the sky and the sea and the prolific amount of flying fish they kept encountering.

One student asked about the most amusing thing that happened on the trip so far. Rich described how they had heard something tapping and scratching on the hull bottom, so he dove into the cold, dark sea where he discovered and removed a giant kelp. While in the water, he got hit right in the face by a flying fish.

Rich spoke at great length to my kids about the importance of pursuing a dream. In answer to the obvious question, "Why are you doing this again?" Rich said that once a person has a goal or a dream he must never give up trying to accomplish it, no matter what obstacles he has to overcome. In his own case, Rich received enormous support from his mother who constantly encouraged him in this endeavor. The fact that he had to provide for the circumstances of his physical disability made his story that much more inspiring.

Second and Third Contacts

We made contact again with the *Great American II* on March 29th and March 30th. We listened as Rich described to the children how wonderful it feels to be out at sea in the clean fresh air while he gazes at the beautiful expanse of water going into an azure-colored sky. He told us that his breathing problem was tremendously improved

because of the clean fresh air. On the second and third contact he answered questions about the differences in construction between this boat and the *Great American I*. He told us about the division of labor between the two men and what it was like to be one half of a two-man crew on a voyage of this duration. He told the children that every team needs a leader (at sea, the skipper) and a chain of command. Bill and Rich decide sail changes and strategic weather routing constantly. When on watch, Bill sails the boat his way, with the proviso that major changes/decisions must fall in the skipper's lap.

One of the most interesting discussions in our contact with Rich took place when I asked him to compare and contrast what he was doing with the work of the astronauts on board a space shuttle. My kids are very much involved with NASA's SAREX (shuttle amateur radio experiment) program. He pointed out many similarities that provided me with material for many follow-up activities and lessons for the class. The children were the ones who commented on how the astronauts and Rich both had a pioneering spirit and were willing to take great risks to achieve their goals.

We couldn't make contact with them after the 30th because rough seas required that they both concentrate on moving the trimaran forward without their attention being diverted. Rich said that although they had computers set

Photo B. Left to right: Mike, Brandy, Barbara and Mike did reports and wrote up questions to qualify to stay after school for the contact with WA1BZE.

up with satellite communications system, he counted on ham radio for his most up-to-date weather information and found that the support of hams along the route was invaluable.

As of this writing, they calculate at least another week before they dock in Boston. We'll all be watching with tremendous interest to see if they break the record. Rich has promised to make arrangements to visit our school and

meet with the youngsters he spoke with on ham radio. What other kind of classroom can you think of that could offer this kind of incredible experience to young people?

[Editor's Note: As we went to press with this issue, Rich Wilson and Bill Biewenga made landfall in Boston on April 7th. Their total time of 69 days, 19 hours, 44 minutes is the new San Francisco-to-Boston record.]

AIRCRAFT RECEIVER KIT ...puts you in the pilots seat!!

Turn into the exciting world of aviation. Listen to airlines, big business corporate jets, hot-shot military pilots, local private pilots, control towers, approach and departure radar control and other interesting and fascinating air-band communications. You'll hear planes up to a hundred miles away as well as all local traffic. The AR-1 features smooth variable tuning of the entire air band from 118 to 136 MHz, effective AGC, superheterodyne circuitry, squelch, convenient 9 volt operation and plenty of speaker volume. Don't forget to add our matching case and knob set for a fine looking project you'll love to show. Our detailed instruction manual makes the AR-1 an ideal introduction to two life-long fascinating hobbies at once - electronics and aviation!

C-AR ...CASE SET FOR AR-1\$12.95

EASY-KEY CW KEYER KIT

- WORKS GREAT ON ANY RIG
- PERFECT CW IN ONE NIGHT
- IDEAL FOR CODE PRACTICE, TOO!

Add to your CW fun with our low cost CMOS Keyer Kit. You'll send clean code that's a pleasure to copy, self completing dots and dashes with properly weighted spacing and timing are all programmed into the CW-7's design. Assembly of the keyer is fast, easy and fun, our step-by-step instructions lead you to a finished unit in only one evening. For beginners, the CW-7 makes an ideal code practice oscillator - learn the sound of perfectly formed CW right from the start and have a fine piece of ham gear, too! Built-in sidetone, adjustable pitch, front panel speed and volume controls and convenient 9 volt operation are featured. The CW-7 is the ideal companion to your QRP transmitters or any other rig you may own. Manual also includes details on constructing economical CW paddles. To give your project a finished, 'store-bought', professional look, use our custom case and knob set that also matches our QRP receivers and transmitters.

LEARN COMPUTER THEORY BY BUILDING THIS KIT DIGITAL TRAINER MODEL MM-8000

Starting from scratch you build a complete computer system. Our Micro-Master trainer teaches you to write into RAMs, ROMs and run a 8085 microprocessor. You will write the initial instructions to tell the 8085 processor to get started and store these instructions in permanent memory in a 2816 EPROM. Teaches you all about input and output ports, computer timers. Build your own keyboard and learn how to scan keyboard and display. No previous computer knowledge required. Simple easy to understand instruction teaches you to write in machine language. Upon completion of this course you will be proficient in computer technology.

- Uses the 8085 Microprocessor
- Uses the 2816 EPROM, electrically erasable programmable ROM
- Uses the 8156C, 2048 Bit static MOS RAM with I/O ports and timer
- Memory expandable option
- Built in 5V power supply
- 28 key keyboard
- Complete with lesson manual, instructions and experiments

Wrap-Up on the Controller Project

This month we'll wrap up some of the loose ends left dangling from our latest project.

There is a terminal block, available from Mouser Electronics (1-800-346-6873; stock number 506-8PCV-04), that fits the PC board and allows for easy connections between the array and the battery. Also, the trimmer used to set the state of charge is a Mouser number ME324-CP10H-470K. You can, of course, use other styles of trimmers, but they won't fit the board. The trimmer used to set the reference voltage is a 20-turn trimmer, also available from Mouser (stock number 594-64W102).

If you can't get the circuit to operate, the first thing to check is the reference voltage. No reference voltage or an incorrect reference voltage will produce a dead controller. By adjusting the trimmer, you should be able to

vary the voltage around the set point of 4.4 volts. Check for +12 volts on the input of the 7812. Also, check for +12 volts on the input of the LM317Z. If you've got that, then the trouble may be with the LM317Z. Be sure you don't have it installed backwards. It's easy to do with the TO-92 case style.

It's also a good idea to check for VCC on each of the chips. Remember, on the LM324, VCC is on pin #4; and on the 4001 it's on pin #14. Also, while you're at it, probe the ground pin. Being at ground, the pin should be zero. If not, then you have a soldering error on that chip. You may also have a broken trace on the PC board.

Double-check for the proper reference voltage on all points requiring it. Now, check for the proper function of the state-of-charge voltage. Adjusting the 470k trimmer should vary the voltage on the output pin of the op amp. If not, then you have either a wiring error or a bad section of an op amp. If you have the chip in a socket, swap it out with another one and retest the circuit.

Check to see if you have the required +20 volts on the gate of the

FET when the charging LED is on. If not, then you have either a bad 4001 or a problem in the voltage multiplier diodes. Use an oscilloscope and check the output of the oscillator. It should be a 2 volt peak square wave. Also, both of the control pins on the 4011 must be low when the charging LED is on. If not, then work back to the op amp switch. Swapping out an IC to find a bad op amp or gate is the best troubleshooting method for this section.

If everything seems fine but you still can't pass current, re-check the connections between the MBR1635 and the power MOSFET. Notice that the MBR1635 leads are backwards compared to most diodes. Some 1635s have a diode symbol to show what lead is what. See Figure 1 for a clearer view on how to connect the MBR1635 and the power FET.

You can expand the current capacity of the controller by increasing the current capacity of the blocking diode and the power MOSFET. An SD51 will handle up to 45 amps of current. You can add more power MOSFETs in parallel to increase current capacity and to lower the overall RDS(on) of the FETs.

Final Advice

First, this is by no means the best circuit in the world and there will always be room for improvements. I'm

not totally happy with the gate driver as it is not fast enough to fully turn off, causing some distortion. A better driver circuit would improve operation. Also, I noticed some of the harmonics from the voltage pump appearing on the gate of the FET. Adding a 0.001 cap from the gate to ground shunts this stray RF to ground, but it also adds extra capacitance to the FET gate. I'm working on a voltage pump using a small transformer to totally remove any RF from the system. Yes, there are special high-side driver chips on the market, but they're expensive and hard to get right now.

By breaking the connection from the 100k 1% resistor and the 20k 1% resistor from the PC trace you can use remote battery sensing. This point would then connect directly to the battery and not to the terminal block on the PC board. One more LM324 would give us low battery sensing, too, or perhaps a low voltage disconnect. Perhaps on the second generation I'll include these features.

I've noticed a bit of a bug every now and then in the over-temperature shutdown. I can't place my finger on it, but it looks like an offset problem with some LM324s. At very low battery voltage the over-temperature shutdown won't! As the battery's voltage increases, everything works as planned. I'm working on the problem.

The controller will work with a com-
